P R O C E E D I N G S

Time: 8:32 a.m.

CHAIRMAN POWERS: The meeting will now come to order. This is the meeting of the Advisory Committee on Reactor Safeguards.

ACRS members in attendance are Bill Shack, Sam Armijo, John Stetkar, Harold Ray, Otto Maynard. Derek Widmayer of the ACRS staff is the Designated Federal Official for this meeting, and I left out Mario. Mario showed up. The esteemed Chairman of the ACRS himself is here to watch and monitor and assess my importance.

Mike Ryan is here, but Mike -- did we ask you? Good, glad to have you here.

The Subcommittee will hear presentations and hold discussions with representatives of AREVA, NP, the NRC staff and interested persons regarding this matter. This is an information only briefing to the Subcommittee.

The Subcommittee will gather relevant information today and report to the full Committee later on this week, actually Friday, but will not be formulating any findings on these matters at the conclusion of this meeting. In fact, what we

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

(202) 234-4433

www.nealrgross.com

1 are just doing is beginning our process of going
2 through design certification on the EPR.

3 In that regard, I am going to ask the
4 speakers at the beginning of your presentations to
5 give us a little background, because we are going
6 to be with you for a protracted period of time,
7 and it would be useful to know something about you
8 here.

9 So if you would just do that at the
10 beginning of your presentation, we usually say why
11 are you qualified to speak before this august
12 body, and just because we are going to be together
13 for several committee meetings, I suspect, and it
14 would be useful to the members to know. The
15 members will not reciprocate, by the way. We have
16 no intention of telling you why we make up such an
17 august body.

18 The purpose of the meeting is to
19 provide background information on two key
20 technical areas which have been of interest to the
21 staff during the review of the US EPR design
22 certification.

23 The staff and AREVA both wish to
24 introduce the ACRS Subcommittee members to these
25 technical areas at this early date while the draft

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 safety evaluation report chapters are being
2 completed. The Subcommittee will review these
3 matters again when the relevant chapters of the
4 draft safety evaluation report come to the
5 Subcommittee for formal review.

6 Rules for participation in today's
7 meeting have been announced as part of the notice
8 of this meeting previously published in the
9 Federal Register. We have received no written
10 comments or requests for time to make oral
11 statements from members of the public regarding
12 today's meeting.

13 A transcript of the meeting is being
14 kept and will be made available, as stated in the
15 Federal Register notice. Therefore, we request
16 that participants in the meeting use the
17 microphones located throughout the meeting room
18 when addressing the Subcommittee. The
19 participants should first identify themselves, and
20 speak with sufficient clarity and volume so they
21 may be readily heard.

22 Copies of the meeting agenda and
23 handouts are available, actually, in the front of
24 the meeting room.

25 There is a telephone bridge line that

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 has been established for the meeting room today,
2 and I understand that we have participants from
3 AREVA and NRC staff on the lines. We do request
4 that participants on the bridge line identify
5 themselves when they speak, and to keep your
6 telephones on Mute during the times when you are
7 just listening and, if you can't figure out how to
8 do that, Mr. Widmayer will be glad to explain the
9 subtle details of *6 to you.

10 We can begin with the meeting now. I
11 will first of all ask, are there any members of
12 the Subcommittee that want to make opening
13 statements? They are mute on this subject. They
14 have pressed *6 apparently.

15 Again, it would be useful if speakers
16 would give us a little bit of background when they
17 talk. I will turn now to Mr. Tesfaye who will
18 speak on behalf of the staff.

19 MR. TESFAYE: Good morning, Mr.
20 Chairman. My name is Getachew Tesfaye. It is
21 pronounced just like it is spelled here, Getachew.

22 I will give you a little bit of background for
23 myself.

24 I have been with the NRC for five
25 years. Prior to coming to the NRC, I was a

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 licensing engineer at Calvert Cliffs Nuclear Power
2 Plant for 16 years -- Calvert Cliffs. And I was
3 involved in several major project management
4 activities at Calvert Cliffs.

5 Here at the NRC, I spent my first year
6 doing containment evaluation, and have been the
7 project manager since the application was
8 submitted in December 2007. Is that enough for
9 background, Mr. Chairman?

10 CHAIRMAN POWERS: That will do.

11 MR. TESFAYE: Thank you.

12 CHAIRMAN POWERS: Give us what you
13 want.

14 MR. TESFAYE: Just a short presentation
15 to give you a status of where we are at with the
16 design certification review. As I said earlier,
17 the application was submitted on December 22,
18 2007. This is a six-phase review process.
19 Unfortunately, I don't have the slides on the
20 screen, but I have a handout of the slides.

21 We have completed Phase 1 of the
22 review, which is preliminary safety evaluation
23 report with RAIs, and in that process we generated
24 close to 2500 RAI questions, and that phase was
25 completed on time.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 We are currently in Phase 2. The
2 target for completing Phase 2 is June 30, 2010.
3 We have already completed two chapters of Phase 2
4 and issued SERs with open items. Those are
5 Chapter 2 and Chapter 8. We plan to complete
6 Chapters 11 and 10 within the next few weeks. As
7 I will show you in the next slide, those four
8 chapters will be the first one that will be
9 formally presented to the Subcommittee and the
10 full Committee in November.

11 Phase 3 is targeted to be completed
12 September; Phase 4, Advanced SER with No Open
13 Items in April of 2011; and then Phase 5 is ACRS
14 review of Advanced SER with no open items, July
15 2011, and the final SER with no open items is
16 scheduled to be completed in September of 2011,
17 and the rulemaking in February of 2012.

18 Go to the next slide, please.

19 Our plan for Phase 3 ACRS review is:
20 We have divided the chapters into four groups,
21 four major groups. The first group, as I
22 mentioned earlier, will be presented in November.
23 Those are Chapters 2, 8, 10 and 12.

24 I guess, for the sake of people who
25 don't have access to my slides, Chapter 2 is site

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 characteristics. Chapter 8 is electric power.
2 Chapter 10 is steam and power conversion, and
3 Chapter 12, radiation protection.

4 The second group is a big group. So we
5 have divided it into two subgroups. The first
6 subgroup will be presented in February. That is
7 going to be Chapter 4, Reactor; Chapter 5, Reactor
8 coolant and connected systems; and Chapter 16,
9 Tech Specs, and Chapter 17, quality assurance.

10 In group 2, we have Chapter 11 and
11 Chapter 19. Chapter 11 is rad waste management.
12 Chapter 19 is severe accidents and PRA.

13 In Group 3, which is currently
14 tentatively scheduled for May 2010, we have
15 Chapter 3, design of structures, components and
16 equipment; and Chapter 7, instrument and control
17 systems; Chapter 9, auxiliary systems, and Chapter
18 18, human factors.

19 The final group will be presented in
20 July 2010, and that will be Chapter, general plant
21 description; Chapter 6, engineered safety
22 features; Chapter 13, conduct of operations;
23 Chapter 14, initial test programs, and Chapter 15,
24 safety analysis.

25 The last presentation to ACRS in this

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 Phase 3 will be in September. This will be a
2 summary, and again this is tentative. If there is
3 no need, we may not have that meeting in
4 September. What we plan to do at that summary is
5 give you the status of all open items, any cost
6 cutting issues, and revisit earlier chapters as
7 needed.

8 That is our plan for Phase 3.

9 MEMBER SHACK: The dates in
10 parentheses, those are dates you completed the
11 draft?

12 MR. TESFAYE: Yes, open items. No, no,
13 no. The dates in parentheses in the tables?

14 MEMBER SHACK: Oh, yes. You've got a
15 color. I've got a black and white. Okay.

16 MR. TESFAYE: You are right. The one
17 next to the chapters?

18 MEMBER SHACK: Yes.

19 MR. TESFAYE: Yes. That is all I have.
20 Is there any questions for me?

21 CHAIRMAN POWERS: I don't know that we
22 have any questions.

23 MR. TESFAYE: Thank you.

24 CHAIRMAN POWERS: I appreciate the
25 schedule, though. I don't guaranty that we will

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 follow it, but it gets us started on this process.

2 Thank you.

3 MS. SLOAN: All right. Thanks.

4 By way of introduction, my name is
5 Sandra Sloan with AREVA. My current
6 responsibilities are: I am the Manager of
7 Regulatory Affairs for New Plants. What that
8 means in practical terms is I am responsible for
9 providing licensing support for all US EPR
10 projects. Obviously, the focus of my group is US
11 EPR design certification, but we also provide
12 support to our combined license applicants as
13 well.

14 By way of background, I started my
15 career at the Idaho National Lab, spent six years
16 there doing thermal hydraulics and safety
17 analysis, and then went on to AREVA and its
18 predecessor companies where I have been for the
19 last 12 years, and transitioned to licensing
20 related work about six years ago. And as I get
21 told frequently, I am not very technical anymore
22 as a licensing person, but I do like to think that
23 I remember something from my thermal hydraulics
24 and safety analysis background.

25 CHAIRMAN POWERS: We'll try to get rid

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 of that. How many COL applicants do you think you
2 will have?

3 MS. SLOAN: You mean ever or do we have
4 right now?

5 CHAIRMAN POWERS: As you see it, where
6 is the world right now?

7 MS. SLOAN: Well, right now the active
8 applicants, obviously, are Calvert Cliffs for
9 Unistar, Bell Bend for PPO. Nine Mile Point has
10 been submitted and accepted for review, but the
11 start of the review has been sequenced or
12 deferred, whichever word you choose to use, to
13 September of next year.

14 Of course, Callaway was submitted and
15 accepted for review, and has asked the staff for
16 now to suspend the review, and the staff has
17 agreed to suspend the Callaway review for the time
18 being.

19 CHAIRMAN POWERS: Keeps you busy,
20 presumably.

21 MS. SLOAN: Well, very busy, yes.

22 So our goal today, based on our
23 interactions with the support staff, primarily
24 with Derek, and in talking with the NRC staff --
25 Our goal was, as you said, to provide you some

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 background information.

2 We understand this is the beginning of
3 what we hope is a long and very successful
4 relationship with the ACRS Subcommittee.

5 CHAIRMAN POWERS: We hope it is brief
6 and successful.

7 MS. SLOAN: Briefer is better.

8 CHAIRMAN POWERS: We anticipate it will
9 be warm, but we don't want to prolong it.

10 MS. SLOAN: Good. So in that vein, we
11 decided we wanted to give you some background
12 information. We realize this is not the end-all,
13 and there will be other discussions on these
14 topics, but what we had hoped to do was at least
15 give you an overview in two key topic areas that
16 have been of particular interest in the review,
17 one of them being containment design and analysis,
18 which we have had quite an extensive series of
19 interactions with the NRC staff. So Marty Parece,
20 who is our Vice President of Technology, will be
21 talking about that.

22 Then also, based on some expressed
23 interest, we decided to talk just a little bit in
24 the afternoon about our safety analysis
25 methodologies. Our objective, again, is to give

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 you some background information that, hopefully,
2 will be helpful to you as you get the SER with
3 open items for the chapters from the staff.

4 So the way this is divided up, as shown
5 on the agenda, what we planned is the morning
6 session would focus on containment design and
7 analysis. There will be an open session for the
8 public, and then there will be a closed session
9 where we will go into more details about the
10 evaluation model that we are using for the mass
11 and energy releases as well as the containment
12 pressure and temperature response

13 Then after lunch we will come back and
14 talk safety analysis methodologies, and that will
15 be again formatted with an open session where we
16 will give you a broad overview of the design and
17 particular design features that are important,
18 particularly important or unique, when it comes to
19 safety analysis for EPR, and give you some
20 insights on why we selected the methodologies we
21 did, and at least an overview of how we
22 demonstrated applicability of the methods for EPR.

23 Then in a closed session, we elected to
24 focus on three key methodologies, and we put a lot
25 of thought into which methodologies we would use

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 this time. We realize the time is somewhat
2 limited, but we used the criteria of did a
3 methodology, as in the case of control rod
4 ejection, need to be updated or changed on the
5 basis of new regulatory expectations, in this case
6 the new SRP acceptance criteria and guidance.

7 So there was a methodology developed
8 specifically for EPR for control rod ejection,
9 which reflects the new SRP acceptance criteria.
10 Then we will spend some time talking about large
11 break LOCA. We use a realistic large break LOCA
12 methodology for EPR, and we submitted a topical
13 report to the staff. It is a specific application
14 of the realistic LOCA methodology for EPR.

15 So we would like to talk some about
16 that, and then spend some time at the end talking
17 about small break LOCA, simply because, as you
18 will hear in the design overview, there are a
19 couple of design features which, at least
20 initially -- in particular, the partial cooldown
21 of the generators and the use of medium head
22 safety injection caused some slightly different
23 response in the early phases of a small break
24 LOCA.

25 So that's the topics that we picked and

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 why we picked it. I hope that helps. I did want
2 to call attention to the fact that in your slide
3 package, behind my slides there is a list of
4 acronyms. We tend to talk in alphabet soup. So
5 often we find it is helpful to have a decoder
6 ring. So I would encourage you, if we use
7 something and it doesn't make sense to you -- the
8 acronym doesn't make sense -- obviously, stop us.

9 But this is sort of the decoder ring. Hopefully,
10 we covered all the acronyms that we will use
11 today.

12 CHAIRMAN POWERS: A committee that goes
13 by the name ACRS is not unfamiliar with
14 abbreviations.

15 MS. SLOAN: Good. Unless there are any
16 questions, generally speaking, about what we have
17 done in design certification, I will turn it over
18 to Marty Parece.

19 CHAIRMAN POWERS: I would just inject
20 that we will go into closed sessions a couple of
21 times today, and the pressure is on you to see
22 that everybody in the room is qualified to be
23 here. Derek will take care of the mechanics, but
24 you've got to vet the people.

25 MS. SLOAN: Okay, got it.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 CHAIRMAN POWERS: And you would
2 probably kick me out on that basis, and that would
3 be good. Marty?

4 MR. PARECE: Okay. As you have heard,
5 my name is Marty Parece. I am the Vice President
6 of Technology. In that position, my organization
7 is responsible for the configuration control of
8 all new reactor products in North America,
9 including EPR and work we are doing on our gas
10 reactor product with BEA and the DOE.

11 In that vein, many of the design
12 features we are going to talk today is part of our
13 goal of keeping converged with the worldwide
14 design. We would like to standardize as much as
15 possible with the European fleet.

16 My background: I started with a
17 precursor company of AREVA, Babcock-Wilcox, in
18 Lynchburg, Virginia, 27 years ago, and my
19 background started in safety analysis and plant
20 analysis, including all types of PWRs, and I have
21 had a very broad background.

22 So I tend to be more of a generalist
23 these days than a specialist in any one thing, but
24 I was the architect of our power up rate and steam
25 generator replacement licensing technologies and

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 approaches, and I have worked on emergency
2 operating procedures, component design, large
3 licensing projects, small projects, and I have
4 always kept my toe in the technology, the R&D, the
5 codes and methods that we are applying.

6 That is one of my responsibilities now
7 as Vice President of Technology. I am responsible
8 for coordinating our R&D programs.

9 So that is my background. is that
10 sufficient?

11 CHAIRMAN POWERS: It is a start, Marty.

12 MR. PARECE: Okay. Next slide, please.

13 So in this open session, we are going to talk
14 about the containment design features and the
15 layout of the containment, so that you get a good
16 feeling for what the containment looks like and
17 where things are and how it works during a
18 postulated event, and we are going to do a summary
19 of the evaluation model.

20 Then in the closed session, we will go
21 into more details on the evaluation model.

22 CHAIRMAN POWERS: One of the great
23 philosophical issues ACRS now wrestles with is
24 that this isn't the first EPR in the world, and
25 presumably other regulatory bodies have examined

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 this containment in some detail. Particularly, I
2 know the Finns looked at it in some detail.

3 One of the great philosophical issues
4 that the Commission certainly wants to wrestle
5 with -- I don't know whether the ACRS does or not;
6 I look at Mr. Bonaca on this -- is how much of
7 that do we just take on faith? I mean, they
8 looked at it. Why are we looking at it in detail?

9 As it comes up, it would be useful to
10 know where things are going to stand, and in great
11 detail, and what your feelings are on the need to
12 pursue some of these things in depth. It is an
13 issue that we've got to wrestle with.

14 We understand that the nuclear business
15 is becoming very international in character, and
16 you know, there's been some things that an
17 American plant, or a European plant or a Japanese
18 plant -- they are all kind of like everybody in
19 the world's plant. So how much duplication of
20 effort do we have to go through on these things,
21 and how much can we say, okay, well, you know --

22 For instance, Sloan, in your area of
23 thermal hydraulics, I bet you the French go
24 through thermal hydraulics, that they are fairly
25 detailed, and I know for sure the Finns looked at

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 containment a little bit.

2 MR. COLACCINO: Dr. Powers, if I could
3 interject here. I would just like to introduce
4 myself. My name is Joe Colaccino.

5 I am the Chief of the EPR Projects
6 Branch. Just to follow through with what you
7 asked for, my responsibilities are to manage the
8 branch that is doing the design certification, the
9 four COLAs that we have, Calvert, Bell Bend, and
10 the two suspended ones that we were mentioned,
11 Nine Mile and Callaway.

12 I just wanted to bring up the
13 activities that the staff is involved with in the
14 Multi-national Design Evaluation Program or MDEP.

15 EPR is a particularly active as an
16 active sub-working group. We are meeting with
17 regulators from Finland, France, the UK, Canada,
18 and just recently China, biannually, every six
19 months, to discuss where the regulators are in
20 their reviews. We are exchanging information.

21 There are three technical expert
22 subgroups that are within that expert group. One
23 of them is on accident analysis, which does include
24 containment. One is digital INC which the NRC is
25 the lead for. One of the NRO branch chiefs is

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 Terry Jackson who, I believe, has appeared before
2 the Committee before. The third group is the -- I
3 believe it is the PRA Subgroup.

4 So those technical expert subgroups
5 meet separately with the exception of the
6 containment one. The containment one is really
7 meeting in conjunction with a main working group.

8 So there is significant discussion that
9 is going on between the regulatory bodies of all
10 the nations that are either in the process of
11 deploying EPRs or thinking of deploying EPRs.

12 So there is quite a bit of discussion
13 that is going on, and so I understand your
14 comments. It is completely understandable. I
15 just want you to know that the staff is working
16 with the other regulatory bodies that are working
17 on doing EPR licensing.

18 I would just make one observation. We
19 are kind of all in an interesting time -- I think
20 I would say "all" -- the Finns, the French and the
21 U.S., because even though we are in different
22 stages of our licensing processes, we are actually
23 all converging at about the same time. We are
24 making decisions.

25 It is kind of interesting. Our Part 52

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 licensing process, driving decisions earlier in
2 the decision making, is kind of gelling with where
3 the Finns and the French are. They are in the
4 middle of construction right now, but they haven't
5 received the operating license applications.

6 So they are looking at things, and we
7 are looking. It is actually kind of an opportune
8 time. So we are trying to take as much advantage
9 as we can out of these interactions.

10 CHAIRMAN POWERS: I appreciate your
11 comments. In fact, it would probably be useful to
12 have a presentation from you at sometime on
13 exactly the activities that you speak of.

14 MR. COLACCINO: I was anticipating that
15 you would have that, and I would offer that at
16 some point. I would suggest probably sometime
17 next year, if we had our meeting in December.

18 The NRC staff has initiated several
19 calls on other topics, because as Getachew said,
20 we are producing -- I want to emphasize what we
21 are producing right now. It is a safety
22 evaluation report with open items. It is not a
23 draft safety evaluation report.

24 In fact, one of the safety evaluations
25 that we have issued, Chapter 8, has no open items

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 in it. I consider that final. You know, unless
2 someone makes a change or, in the context of doing
3 a review, that we find something else, I don't
4 expect to look at it again.

5 CHAIRMAN POWERS: It is really quite
6 interesting, and maybe you guys can figure out
7 some time and we can hear about what all they are
8 doing. That is useful.

9 MR. COLACCINO: Okay. I would expect
10 in the spring of next year is probably a more
11 appropriate time to come with that.

12 CHAIRMAN POWERS: I would think that is
13 probably the earliest we can schedule it anyway.

14 MR. COLACCINO: Yes, sir.

15 CHAIRMAN POWERS: But I appreciate your
16 comments, and we are going to try to follow up on
17 that.

18 MR. COLACCINO: Thank you.

19 CHAIRMAN POWERS: Similarly, I would
20 like to get AREVA's thoughts on these subjects, as
21 they come to mind.

22 MR. PARECE: Next slide, please. So we
23 are on slide 11 in the package now, and this just
24 gives you an overview of the containment design
25 parameters.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 You may have seen this in our last
2 presentation of the overview of the plant, but we
3 just want to point out: The reactor building
4 system is comprised of a containment building, a
5 post-tensioned containment building, concrete
6 containment building with tendons, and also has a
7 quarter-inch steel liner, and it is surrounded by
8 a shield building that is reinforced concrete to
9 protect the containment from external hazards.

10 The volume is about 2.8 million cubic
11 feet, which makes it similar in size to large
12 containments here in the U.S., and we give some
13 dimensions there: About 153 feet in diameter on
14 the inside. We will be talking about the
15 containment building and its performance today,
16 not the shield building in particular.

17 The design pressure is 62 psi gauge,
18 which is a little higher than some units, and that
19 design pressure was selected purposely based on
20 the design basis events and certain beyond-design
21 basis events.

22 So this design: We have in-containment
23 refueling water storage tank, and that is typical
24 of a lot of advance reactors. It is down in the
25 bottom of the containment so that liquid collects

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 in the bottom of the containment during events as
2 the condensation occurs. I am pointing it out
3 down here.

4 Also we have features for issues
5 regarding GSI 191 in this floor. We are going to
6 talk about this floor. It is called the heavy
7 floor, and we are going to discuss that today.

8 The reason we call it the heavy floor
9 is that the steam generators, the pumps, the large
10 components -- the supports actually sit on that
11 floor. So that floor supports the steam
12 generators and the pumps, and thereby supporting
13 also the coolant lines.

14 In that floor, we have large holes for
15 water to drain down to the IRWST from a postulated
16 break inside that containment, and we have racks
17 over those holes to prevent large debris from
18 getting into in-containment refueling water
19 storage tank.

20 Also, below those holes we have baskets
21 so that water and debris that goes in the basket
22 fills the basket and spills over the top. So
23 large debris gets collected in the basket.

24 Then inside the IRWST we have strainers
25 for the emergency core cooling system that takes

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 suction off the IRWST, and those strainers have a
2 very small mesh, and we have features, back end
3 angled strainers, so that caking tends to fall
4 off, and we can also -- We have flushing that we
5 can have, active flushing from the ECCS system to
6 flush the strainers.

7 So it is a very robust approach from
8 that point of view, and that is all in this area
9 here, inside the equipment space.

10 MEMBER SHACK: Do you have a rough
11 square footage of strainer area or are you
12 depending on the black flushing?

13 MR. PARECE: No. We count on the size
14 to keep the delta P low, and those -- We had to
15 revise the design a bit because of the seismic
16 requirements. At OL3 the seismic is 0.1g, and we
17 are designing 0.3g. So we wanted to beef up the
18 design from a seismic point of view, because these
19 are safety related.

20 So we have made some adjustments to the
21 design, and we've got testing at Alden Labs later
22 this year to finish that design up. The OL3
23 design has been tested with and without debris to
24 characterize the delta P. We are going to do the
25 same types of testing, but on this beefed up

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 design.

2 The area is generally significantly
3 more area than we need, and that is generally the
4 design approach. The holes in the heavy floor and
5 the baskets and all of that are based on our 4 by
6 100 design.

7 So we tend to oversize and keep delta
8 Ps low and keep the flow areas large, because
9 during severe accident we also count -- and we are
10 going to talk about that in a moment. In severe
11 accident we count on hydrogen mixing and air
12 mixing through circulation through the large holes
13 in that floor. So we've got water draining down.

14 We've got vapor coming up. So we oversize all
15 those holes.

16 MEMBER SHACK: Plus you are mitigating
17 the large break LOCA. Is that unique to the EPR
18 or is that a carryover?

19 MR. PARECE: I would say that it is --
20 I wouldn't call it a carryover. I would say it is
21 a combination. The design philosophy for the EPR
22 was to take the best of the French and German
23 designs, and at the time this started, that was
24 the N4 and the Convoy.

25 So the German and French engineers

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 worked together on trying to take the best from
2 the different units, and when you look at
3 individual design features, you can see that.

4 This is truly a combination of
5 approaches and, as we talk about it later, we will
6 talk about hot leg injection during the LOCA, and
7 that is a uniquely German approach to mitigating
8 the event, and we will discuss that. But it has
9 been adjusted based on the French approach as
10 well.

11 The design leak-rate for the
12 containment is about a quarter of a percent per
13 day. That is, in fact, set up based on the
14 radiological approach, and we are not going to
15 talk about the radiological today very much, if at
16 all, but I just wanted to point out that any
17 leakage through the liner into this annulus is
18 filtered.

19 So it goes through iodine filters
20 before it can be released, and any leakage around
21 the penetrations into the surrounding safeguard
22 buildings go into radiological controlled areas
23 where those are also filtered.

24 The fuel building, if you have a fuel
25 handling accident, there is a safety related

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 system to filter that. So all radioactivity
2 releases from EPR are filtered by a safety related
3 system during any postulated accidents.

4 Mouse Click. The EPR is set up with a
5 two-zone containment, two-room containment. This
6 two-room containment is how the plant normally
7 operates. So the red area that you see on your
8 slide is what we call the equipment space, and for
9 obvious reasons, including radiation and
10 temperature, no one is allowed in that space
11 during operation, but the space around it that is
12 white -- you see this area here, the white spaces
13 -- that is called the service compartments.

14 The service space, you can have access
15 at anytime during operation, at power or not.
16 This environment is maintained so that you can
17 have access. So what this means then is, when the
18 plant is operating, it is a two-room containment
19 so that we can control the two areas separately.

20 You can imagine -- and we have -- These
21 compartments are closed on top, and you can
22 imagine, if they were open, the convection -- you
23 would be cooling the whole containment and trying
24 to maintain the whole containment. In this way,
25 we can have one HVAC system cool the equipment

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 spaces and a separate HVAC system cool the service
2 spaces.

3 Those are done with non-safety related
4 HVAC system using chillers with operational
5 chilled water. So the cooling of the containment
6 is a non-safety related function for operation of
7 the unit, and those chillers are inside these
8 service compartments.

9 We also have a -- Well, what we are
10 going to talk about today is how we transition to
11 a single-room containment when there is a loss of
12 coolant accident or other pipe rupture, and we do
13 that using a subsystem with call a CONVECT system,
14 and it has rupture foils and convection foils on
15 top of those steam generator compartments that
16 will open, and we also have dampers in the bottom
17 here near the IRWST that opens, and by opening
18 they basically then connect both sides, both
19 rooms.

20 That allows water vapor and hydrogen
21 and other gases to circulate based on the
22 mechanics of buoyancy due to the warm energy and
23 cooling on the liner and the other containment
24 structures.

25 As part of that then, there is no

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 safety related fan coolers on this unit, and there
2 is no safety related containment sprays. What we
3 will talk about today is how, during an event, the
4 energy from the core and from the sensible heat of
5 the reactor coolant is basically condensed as hot
6 water vapor in the in-containment refueling water
7 storage tank where the heat is then removed by our
8 safety related residual heat removal LHSI systems.

9 So essentially, in accordance with GDC
10 38, our heat removal system is the RHR LHSI
11 system. We will talk about that in detail today.

12 We also have -- For hydrogen control,
13 we have passive autocatalytic recombiners
14 distributed throughout containment. There's 47 of
15 those, I believe, and we use those for hydrogen
16 control. They are predominantly for severe
17 accident. So we won't be talking about the severe
18 accident mitigation features today. We are going
19 to be talking about the containment response to
20 design basis events.

21 That is a good segue. We do have
22 severe accident mitigation -- Yes?

23 MEMBER SHACK: On that severe accident
24 system that you have, that is really a separate
25 cooling system. Right?

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 MR. PARECE: Yes.

2 MEMBER SHACK: There are safety related
3 ones for the design basis accidents, and then a
4 separate -- completely separate system for the
5 severe accident one?

6 MR. PARECE: That is exactly correct
7 for the severe accident. So the severe accident
8 system -- The containment heat removal system is
9 what it is called in Europe. We call it the
10 severe accident heat removal system, because it is
11 just for severe accident. So eliminate confusion.

12 That system has a dedicated component
13 cooling water chain and a central service water
14 chain that dumps the heat to the ultimate heat
15 sink, and that system then is used to mitigate the
16 severe accident, and it is used to cool the
17 concrete below the spreading area and used as a
18 containment spray to reduce the building pressure
19 long term, well after 12 hours.

20 So we could talk a whole day on severe
21 accident, but the main features that we have: We
22 have features to depressurize the unit to low
23 pressure, to prevent a high pressure melt-through.

24

25 We've got the passive autocatalytic

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 recombiners to reduce the hydrogen concentration
2 to prevent deflagrations, and then we have a
3 spreading area adjacent to the in-containment
4 refueling water storage tank where we collect any
5 melt from the postulated core melt and melt-
6 through on the vessel, and then it distributes in
7 a spreading area where it is passively cooled for
8 at least 12 hours due to gravity feed from that
9 in-containment refueling water storage tank.

10 In a nutshell I have given you many of
11 the features for severe accident, but again today
12 we are not talking about severe accident very
13 much.

14 CHAIRMAN POWERS: Is the passive
15 hydrogen system safety related?

16 MR. PARECE: No. I don't believe it
17 is. I'm trying to remember. The guy that would
18 know that is not here today, but I don't believe
19 it is safety related? I don't think we need the
20 passive autocatalytic recombiners to keep the
21 containment inerted during a design basis event, a
22 loss of coolant event. But we do need them to
23 reduce the hydrogen concentration during a severe
24 accident. So they are predominantly to mitigate
25 severe accident.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 CHAIRMAN POWERS: I suspect we will go
2 about a day over the hydrogen recombiners.
3 Indulge us a little bit on that one.

4 MR. PARECE: On Slide 12 we talked
5 about the two-room containment, and the primary
6 way that we transition to a single-room
7 containment is again, as I said, by rupture and
8 convection foils that open on top of the steam
9 generator compartment, as you can see in the
10 picture, up on top of the steam generator
11 compartment, and by dampers that open down near
12 the IRWST elevation. That connects the service
13 space to the equipment space.

14 The convection foils: We have two sets
15 of foils. They sit in a frame, as you can see in
16 the picture. There is a frame, and the rupture
17 foils on a delta P, as they pressurize, they will
18 open, and they don't burst as you would think of a
19 diaphragm bursting. There is a stress riser on
20 them, so that as the pressure goes up, they
21 essentially tear and open up.

22 They can open bi-directional. so if
23 the delta P across the compartment is positive or
24 negative, they will go whichever way they have to
25 go. Those rupture immediately.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 We also have, in addition to those, a
2 number of foils in a frame that, if the
3 temperature exceeds approximately 180 degrees
4 Fahrenheit, they will open. So if you have a
5 small break that pressurizes very slowly and
6 possibly keeps the delta pressure across the foil
7 low enough that it doesn't open, eventually the
8 temperature will cause these to open. Next slide.

9 Slide 13 shows one of these installed.

10 MEMBER STETKAR: When you say
11 temperatures open it, is that an active type
12 opening?

13 MR. PARECE: No, it is a passive --

14 MEMBER STETKAR: Fusible link type?

15 MR. PARECE: Fusible link, and it
16 basically melts.

17 MEMBER STETKAR: Thank you.

18 MR. PARECE: In fact, if we look at
19 Slide 14, that shows what happens.

20 So what is interesting about the
21 convection foils is that they are actually made up
22 of rupture foil. So if the pressure goes up, they
23 will rupture.

24 If we go back one slide, on Slide 13
25 you can see that those are rupture foils in the

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 middle of that frame. So if the pressure goes up,
2 they will rupture, but if the pressure goes up
3 very slowly on temperature, then they will open.

4 A small break then also pressurizes
5 more slowly, puts energy in containment more
6 slowly, and the requirement isn't to mitigate the
7 building pressure immediately. Their environment
8 is just to provide a long term circulation path.

9 MEMBER MAYNARD: How critical is the
10 integrity of these for normal operations? If
11 there is a tear or something during normal ops,
12 what impact does that have on normal operations?

13 MR. PARECE: Well, essentially -- That
14 is a very good question. You would have to,
15 during the outage, inspect these visually and make
16 sure that they are all intact. The biggest issue
17 is -- The answer to your question is "depends."

18 The biggest issue, if keeping them
19 closed, is warm air from the equipment space
20 getting into the service space and then affecting
21 how well you can cool the service space, but that
22 is a primary issue. So if you have a rupture foil
23 that is open, then you probably have to replace it
24 for operational concerns.

25 From a safety concern, obviously, open

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 would be the way to be. So it is not like a tech
2 spec issue where, if one is open, you couldn't
3 start up the unit, but if you get convection
4 currents through there that is causing heat to go
5 in your service space, you are going to tax your
6 HVAC system and your ability to keep the
7 temperature in a habitable zone.

8 MEMBER STETKAR: Would it also affect
9 accessibility from a dose perspective? Personnel
10 -- because you do normally have operators
11 inspecting at least the accessible areas.

12 MR. PARECE: Yes. The expectation
13 would be, if you had one of two of these foils
14 torn, it would not be a significant change in the
15 dose field, but we do maintain the dose field
16 relatively low, even in operation in that service
17 space.

18 The design goal for the EPR is less
19 than 2 mr per hour. So it might have some small
20 effect, but it wouldn't be significant. The big
21 thing is, from an operational point of view, if
22 during an outage someone damages one, you would
23 want to replace it. And they are in frames, and
24 they are easily replaceable.

25 We have tested these foils. We have

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 pressure tests, and we have temperature tests. So
2 we have a fairly extensive testing on them, and I
3 brought a little show and tell with me.

4 Now this is one that has been tested,
5 and we can pass this around to look at it, but
6 we've put some tape on it. Be careful. It is
7 sharp. So as Sandra said, we don't want any OSHA
8 reportable events here today, but you can see.
9 This goes into the frame that you saw, and this is
10 one of the rupture foils that we tested.

11 It is fairly sturdy stainless steel,
12 but I don't remember the thickness. Anyway, the
13 rupture pressure on these is about 0.7 psi plus or
14 minus about 30 percent. We will pass that around.

15
16 There are 120 convection foil units,
17 and there's -- got to be 28 times 4 is 112 rupture
18 foils. So there's 30 units per loop and 28 units
19 per loop respectively between convection and
20 rupture foils. I will show you later how they are
21 arranged when we go to the proprietary session.
22 We can do more details on the data.

23 Next slide. So the way these foils
24 perform then is for large breaks, all the foils
25 open, and for small breaks, there will be a

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 mixture; and as you go smaller in size, you will
2 eventually transition to convection foils. They
3 just provide the long term recirculation.

4 As you can tell from the example we are
5 passing around, no debris is generated from the
6 rupture of those foils, because it is all self-
7 contained and attached. It stays attached, once
8 it ruptures.

9 They are safety related. They are
10 designed to meet seismic requirements, because we
11 need them to operate during the design basis LOCA.

12 Back up a couple of slides. We've talked a lot
13 about foils.

14 The hydrogen mixing dampers: Here is a
15 picture of one you can see at the bottom of Slide
16 12. There's eight of those spaced around
17 containment, and they open on a differential
18 pressure between the service space and the
19 equipment space around a half a psi, but they will
20 also open on a global pressure.

21 So if the containment pressure -- Right
22 now that set point will be set by the safety
23 analysis, but right now it is about 5 psi. At 5
24 psi gauge, they will also open. So these are
25 spring loaded, and they are held shut.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 The I&C system, when it detects -- I
2 should say our digital protection system, when it
3 detects a high building pressure, then it will
4 send a signal to the dampers to open, and then
5 they fail open on loss of power.

6 Next slide.

7 MEMBER SHACK: They will blow open on
8 the global pressure?

9 MR. PARECE: Yes, on the global
10 pressure, when you hit 5 pounds, they will open.
11 But if you get a delta P in the equipment spaces,
12 they will open. So again, if you have a fairly
13 large break, anything above 4 or 5 inch break, you
14 are going to get a delta P, and they are going to
15 open. If you have something that is really small
16 and the convection foils open first and you start
17 venting vapor to containment, you will slowly
18 start pressurizing the containment, and eventually
19 you will hit the pressure set point for
20 containment, and the dampers will open.

21 CHAIRMAN POWERS: On your previous slide, on
22 Slide 15, it says MAAP4 analyses addressing CFR
23 50.44 show good mixing.

24 MR. PARECE: Yes. That is true, but
25 what we are going to talk about today is we are

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 going to talk about a number of analyses that have
2 been performed. I wasn't going to talk about the
3 MAAP4 analyses, because those were for severe
4 accident, and in that case you are looking at the
5 performance, but you are looking at the hydrogen
6 mixing, in particular.

7 CHAIRMAN POWERS: Where in the MAAP4
8 has -- treats the momentum equation as a lump node
9 code. So you had to assume good mixing to get the
10 answer to good mixing.

11 MR. PARECE: Well, that is a
12 possibility. I didn't do the severe accident
13 analysis, but what we are going to talk about
14 today is we have other codes between GOTHIC, and
15 we are going to talk a little bit about other
16 qualifications like GASFLOW, which is a Los Alamos
17 code, and we've got some global analysis that
18 we've performed.

19 So we are going to talk specifically
20 about mixing and what we are predicting with
21 these. So we are going to talk in more detail.

22 CHAIRMAN POWERS: I hope that there is
23 something to substantiate that?

24 MR. PARECE: Yes, there is.

25 MEMBER RAY: You talked about

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 qualification testing. Have you come to any
2 conclusion about surveillance testing, either the
3 hydrogen or the dampers or the foils?

4 MR. PARECE: Well, yes. We do
5 extensive testing to validate the foils. So we
6 don't expect to do a surveillance test per se on
7 the foil itself. We already have qualification
8 tests on that.

9 What you will have is you will have to
10 do in a visual to ensure that they are in place.
11 On the dampers, you can test those easily by
12 sending a signal from the I&C system, and then
13 watching them open.

14 MEMBER RAY: And you would expect to do
15 that?

16 MR. PARECE; Yes, I would expect to do
17 that, because they are safety related. So we
18 would test those, and it is a relatively easy test
19 to do for the dampers during refueling outages.

20 So we have talked about the convection
21 foils and the dampers and how they will open to
22 connect the containment into two parts. What we
23 are going to talk about then is the overall
24 containment concept and the design concept and how
25 we mitigate breaks, postulated ruptures.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 So if we have a postulated rupture
2 inside the equipment space which will then cause
3 it to pressurize, then the foils will rupture, and
4 the dampers will open, and that allows the energy
5 to get out of the equipment space up into the
6 service spaces and up into the equipment -- into
7 the containment dome.

8 The steam will begin to condense on all
9 of our heat structures, our containment concrete
10 and our containment liner, and that condensation
11 then will flow by gravity back down toward the
12 bottom of the containment where it will drain into
13 the in-containment refueling water storage tank.

14 So now we have warm, saturated water
15 moving into that tank. In the short term, the
16 pressure peak we get from the blowdown is
17 mitigated purely from the physics, the size of
18 containment -- you know, the volume of it and the
19 mass and energy that is in the building. In other
20 words, in the first 30 seconds during blowdown,
21 you can vary the convection.

22 You can vary the condensation by large
23 amounts, and there is very little impact on the
24 peak pressure. The peak pressure is driven by
25 ideal gas law and the energy that you are

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 distributing. So the containment is sized to
2 ensure the blowdown peak is well below the design.

3 CHAIRMAN POWERS: I would hope it is
4 not dependent on the ideal gas law. The gases are
5 minimum idea.

6 MR. PARECE: Well, all right. But I'm
7 trying to simplify the point of view that air is
8 our single biggest contributor to the pressure.
9 Heating that air causes the pressure to rise
10 significantly, and then you have the partial
11 pressure contribution of the water vapor from the
12 reactor coolant system. So those two partial
13 pressures give you your peak.

14 In the longer term, we have actuation
15 of our emergency core cooling system. So we have
16 medium head safety injection pumps that take
17 suction from the IRWST and inject into the vessel.

18 We have low head safety injection pumps that do
19 the same, but before they inject, they pass
20 through our RHR heat exchanger and cool the water.

21
22 So that is our main place to take
23 energy out of the building. We take the water out
24 of the in-containment refueling water storage
25 tank, and we run it through a heat exchanger,

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 which cools it, and then we reinject it into the
2 vessel.

3 So as we do that, we reinject into the
4 vessel, and we set up a circulation where steam
5 from the reactor coolant system goes into the
6 building, condenses on the walls, goes into the
7 IRWST where the RHR system takes the heat out.

8 In the longer term then, at a certain
9 point in the transient for boron concentration
10 control and for steam suppression, we open valves
11 on the low head safety injection that are normally
12 closed and allow flow to go to the hot legs.

13 So we get each of these systems.
14 There's four by 100 systems. So we have four LHSI
15 systems. Each run around 1900 to 2000 gallons per
16 minute each. So when we turn those on, the
17 majority of that flow is rerouted to the hot legs.

18 So at this point, we have subcooled
19 water going into the hot legs and going into the
20 vessel, and essentially causing steam to condense,
21 and we get mixing in the core which causes a
22 reduction in the steaming rate of boiling in the
23 core, and we put warm water out the break, and we
24 eventually suppress the steaming.

25 So in the long term, we get to a point

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 where we are suppressing the steaming -- or stop
2 the steaming in the hot leg, in the core exit,
3 which reduces the steam going around the steam
4 generators through the broken loop to the break
5 site.

6 So once that steam contribution to the
7 containment stops, then we have condensation, and
8 we continue to depressurize. The long term
9 depressurization of the building is assured by the
10 condensation of the vapor on the heat structures.

11 So over the long term, that is how in
12 the design basis phase we transfer the energy from
13 the core to the IRWST.

14 The other thing I would note, on the
15 picture you have on 16, my colleague, Louis
16 Charles, has reminded me that that line that you
17 see from the LHSI that goes to the IRWST actually
18 occurs inside containment, not outside
19 containment. But the point I wanted to make with
20 that little cartoon is that we also send some of
21 the cooled water back to the IRWST. So we are
22 cooling the IRWST as well as cooling the core.

23 Now this is what we have kind of talked
24 about. A key to making the containment approach
25 work, as you can imagine, if you have a cold leg

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 break in particular, it will eventually get to a
2 point where you have steam being produced in the
3 core and, as long as you have steam being produced
4 in the core, that steam will condense on the
5 emergency cooling that is available, but
6 predominantly steam will go through the broken
7 loop through the steam generator and over to the
8 break, and you will have an almost constant steam
9 source to the containment, and without a fan
10 cooler or a spray system, your containment
11 pressure response is based on the ratio of
12 condensation to steam production.

13 As you can imagine, our heat structures
14 will heat up over time, and the efficiency can
15 reduce over time. To suppress the steaming then,
16 the hot leg injection -- and on page 17, this just
17 shows a cartoon of a large amount of ECCS flow
18 coming into the hot leg and into the upper plenum,
19 and then cold water will mix with some of the warm
20 water in the plenum, but a large portion of it
21 will go down the core, one part of the core, where
22 if you have boiling especially but heating on the
23 other part of the core, some of it will mix and
24 migrate to that side of the core. Then warmed
25 water will go up the downcomer and out the break.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 MEMBER STETKAR: Marty, you said the
2 switchover to hot leg injection is manual?

3 MR. PARECE: Yes.

4 MEMBER STETKAR: Is that also in the
5 European version?

6 MR. PARECE: Yes.

7 MEMBER STETKAR: It is?

8 MR. PARECE: It is. It surprises you
9 that the Germans like automation?

10 MEMBER STETKAR: It does.

11 MR. PARECE: Yes. We have a design
12 rule on EPR that says no design basis accident
13 should require a manual operation before 30
14 minutes. So if it is before 30 minutes, it is
15 automated. If it is after 30 minutes, it tends to
16 be manual, and you would follow your emergency
17 operating procedures. We will discuss later, but
18 those switchover times, based on meeting the
19 acceptance criteria, can be anytime after 30
20 minutes and probably anytime before 90.

21 MEMBER SHACK: But globally they will
22 switch at 90 minutes, and in the U.S. we'll switch
23 at 60?

24 MR. PARECE: Well, it is interesting
25 you picked up on that. Yes. Right now, we are

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 discussing with our European colleagues about when
2 would be the time to credit. It is really -- The
3 time that you pick has to be validated by training
4 the operators in the simulators, and so they can
5 get through the EOP steps in that time. We are
6 pretty confident they can do it in 60 minutes. I
7 am very confident they can do it in 90.

8 Today we are talking about the
9 evaluation model and the safety analysis and the
10 design basis accident and the safety related
11 equipment, but obviously, if an event were to
12 happen on a real plant, the operator also has
13 other equipment, and he does have the non-safety
14 severe accident heat removal system that he could
15 use but, obviously, we don't credit that. Next
16 slide.

17 MEMBER SHACK: But his emergency
18 operating procedures tell him he has this system?

19 MR. PARECE: Certainly. His EOPs --
20 Certainly. EOPs take credit for everything you've
21 got in the plant.

22 CHAIRMAN POWERS: We will have more on
23 an adequate exploration of human errors of
24 commission for this plant.

25 MR. PARECE: So on the next slides what

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 I want to do is set us up for the rest of the
2 presentation. So as we talk about circulation
3 patterns and multi-dimensional models and what-
4 not, that in your mind's eye you've got a good
5 idea of where stuff is and where everything is
6 going.

7 So on Slide 18, this shows a section
8 view of the containment, which many of you have
9 seen many times. We've cut it through the steam
10 generator compartments.

11 This bioshield wall here is the
12 separation of the equipment space from the service
13 space, and you can see the reactor vessel is in
14 its own compartment, and we have cut through the
15 refueling canal here.

16 As we talked about, you can just seen
17 the holes in the heavy floor, and down here you
18 can see the strainers. This is the general layout
19 for the containment from an elevation point of
20 view. Next slide.

21 So if we go all the way down in the
22 basement -- If we go down in the basement, you can
23 see here, this is the reactor pit where the
24 reactor vessel is placed, and you can't quite see
25 it, but there is a transfer tube. This is the

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 spreading area, which is a severe accident feature
2 for the corium to spread in case of a severe
3 accident where it can be cooled.

4 This area is our in-containment
5 refueling water storage tank. I will point from
6 both sides. We will have to swivel our heads.
7 Here you can see the footprint here and there and
8 there and there. Those are the footprints for the
9 baskets I talked about that go under the flow
10 holes. So that is the footprint for the baskets.

11 These four rectangles are the footprint
12 for the strainers for the ECCS. So each one of
13 those would be connected to its own line and to
14 its own division. Each division has a separate
15 intake and strainer, of the four divisions. This
16 is our containment wall, and you can see this is
17 our shield wall. Next slide.

18 So now we have moved up, and you can
19 see the heavy floor. This is where the reactor
20 coolant components will sit. We are cutting
21 through the reactor vessel. You can see the lower
22 head, and here are four drain holes that have
23 those baskets. These are the four drain holes
24 that have those baskets -- racks on top. We call
25 the trash racks on top.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 So we have a trash rack on top, and
2 then right below that are those baskets that we
3 showed the footprint for. In a moment you are
4 going to see, this is where our pressurizer relief
5 tank is going to go.

6 MEMBER SHACK: How deep is the basket?

7 MR. PARECE: Oh, you got me. I knew
8 that number. I don't remember. Next slide.

9 So now you can see, we have come up a
10 bit, and now you can see the subcompartments, and
11 there's a few things I want to point out in this.

12 Here our pump compartments are these
13 areas on the quadrant. That is where the pumps
14 are, and here are steam generator compartments.
15 You can see a wall has popped up. Now at the
16 bottom of this wall, it is open, but right here
17 this wall has popped up. What I want to point
18 out is that there is a concrete wall between every
19 hot leg and cold leg, not just between the loops,
20 but between the hot leg and cold leg on a single
21 loop.

22 So there is a concrete wall around
23 every reactor coolant pipe which limits how far
24 your zone of influence would be on a break with
25 regard to debris generation and the effects on our

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 metallic insulation. We use reflective metal
2 insulation.

3 Here you can see the pressurizer relief
4 tank sitting there, and -- Next slide, please.

5 Now you can see the steam generators.
6 We have cut through the steam generators, and you
7 can see the steam generators in their cubicles,
8 and the pumps. You can see the tops of the pump
9 motors. You can see the four accumulators. They
10 are in the service space. So here is one, two,
11 three, four accumulators.

12 The ECCS system is very much like
13 existing PWRs. Each division has an MHSI medium
14 head safety injection, a low head safety
15 injection, and an accumulator. They combine into
16 a single line that goes into each cold leg. So
17 they are connected -- Separate divisions are
18 connected each to its own loop.

19 So there are the accumulators, and you
20 can just see up here in the upper righthand
21 quadrant, we have just cut through the bottom of
22 the pressurizer. So this is where the pressurizer
23 is, in this cubicle here.

24 Then the thing to note about -- This is
25 the refueling canal, obviously. This is a storage

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 location that we use during refueling. This area
2 on the left is for instrument lines that we pull
3 out of the core and other things we store there.

4 This right here, this narrower one,
5 this is the transfer tube and where we bring the -
6 - transfer the fuel between the fuel building and
7 the vessel. So down at a lower elevation there is
8 actually -- there is a transfer tube to the field
9 building. So the field building is south on this
10 arrangement. Next slide.

11 This elevation shows us the operating
12 floor.

13 MEMBER STETKAR: Marty, as long as they
14 are talking, do you do a full core offload refuel
15 or do you just do a fuel shuffle?

16 MR. PARECE: The answer again is it
17 depends. Right now, our outage is designed -- the
18 fuel pool is designed, boration, heat removal.
19 Everything is designed to do full core offload,
20 and that takes about six assemblies per hour. It
21 takes about 40 hours.

22 So we are designed for a full core
23 offload. But given that -- and a full core
24 offload helps you, because if you are doing steam
25 generator inspection or pump seal work, then you

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 just drain down. You don't have to do nozzle
2 dams, whatever. But given that you would do
3 samples of tubes and you would do pump seal work
4 delay maybe every third outage, in those
5 intervening two outages you would want to do a
6 shuffle. So we can do a shuffle as well.

7 So this just shows the operating floor
8 and the slabs that are over the refueling canal
9 during normal operation. Next slide.

10 So you can see the top of the steam
11 generator cubicles and also here is our equipment
12 hatch in the lower righthand quadrant, and that
13 equipment hatch allows you to take large equipment
14 through the fuel building and out through a hatch
15 in the wall, so it can go out of the building, out
16 of the plant.

17 There is our refueling machine parked
18 at the bottom. Next slide.

19 MEMBER MAYNARD: What level is your
20 equipment hatch compared to ground level?

21 MR. PARECE: The bottom of the
22 equipment hatch lines up with the operating deck,
23 which is 19 1/2 -- plus 19 1/2 meters.

24 MEMBER MAYNARD: So above the ground.
25 Okay.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 MR. PARECE: Above, yes.

2 MEMBER SHACK: Can you get a steam
3 generator out without breaking down concrete
4 walls?

5 MR. PARECE: We can get everything but
6 the reactor vessel out without deconstructing
7 anything. That is not just for the containment
8 building. We have a design requirement that all
9 equipment, except there is some equipment in the
10 turbine island -- but all equipment has to be able
11 to be removed or replaced without deconstructing
12 anything in the plant.

13 So we have pre-engineered hall routs
14 for all equipment, and we already have pre-
15 engineered lifting points for all the equipment
16 and, if something is at a lower level, we have
17 grates in the floor. So you can pull the grates
18 out, and you can grab the heat exchanger, for
19 example, and bring it up to the level and then get
20 it out of the building. So there's hatches on the
21 different safeguard buildings.

22 Now the design life of these components
23 is 60 years, but we designed it anyway so that you
24 can replace the major components.

25 The reactor vessel fits through that

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 equipment hatch and can be handled by the puller
2 crane. The thing is, if you noticed how we built
3 up from the bottom, there is concrete around the
4 vessel. So we would have to take out some
5 concrete to replace the vessel. Before we did
6 something like that, we would look at other ways
7 to extend the life of the vessel.

8 So on Slide 25, this gives you a better
9 picture. These blue areas on top of the steam
10 generator cubicles are where we lay out those
11 rupture foils and convection foils, right in
12 there. So you can see, they are also relatively
13 open to the containment up there.

14 This little area right there you can
15 just see, that is actually a storage place for the
16 reactor vessel head during refueling operations,
17 and it has a wall that you can put in place to
18 prevent people from the shine from the head, but
19 it also has a stand, so that you can do
20 inspections on the top or the bottom or do any
21 activity on the head you want off critical path
22 while people are doing other operations. Next
23 slide.

24 So I've just plummeted you back down to
25 the bottom of the building, and this shows the

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 location of the eight dampers down near the
2 bottom. Next slide.

3 This kind of shows you what it looks
4 like down there, kind of a three-quarter angle
5 shot of the dampers. So you can see where they
6 are, obviously, below the heavy floor but above
7 the IRWST, the in-containment.

8 Let me step closer to the microphone.
9 Next.

10 So we've got an overview of what the
11 containment looks like and what makes up the
12 equipment service spaces and where the dampers and
13 the foils are. So let's talk a bit about the
14 methodology that we are using to analyze the
15 design basis accidents for the containment.

16 We submitted a Technical Report to the
17 NRC, ANP-10299, and in that report there is a lot
18 of mileage in that report on validation of the
19 evaluation model, including the evaluation model
20 development and assessment process (EMDAP).

21 So we describe the M&E, mass and energy
22 release models that we are using and the GOTHIC
23 models and approaches that we are using for the
24 containment response, and also looking at
25 uncertainty analysis, and we have discussed our

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 scaling methodology.

2 If I am correct, we have a Revision 2
3 of this coming in December, which will have the
4 results of the of the scaling analysis.

5 We are going to go into it in a moment,
6 but we -- As part of the uncertainty -- We did an
7 uncertainty analysis. We will talk about the
8 PIRTs that we looked at for mass and energy
9 release and for containment, and that PIRT -- As
10 you know, doing that phenomenon importance ranking
11 table is a thought exercise by experts based on
12 what they know and the state of knowledge of the
13 different phenomena.

14 That is what I would consider to be a
15 top-down approach. We also, by doing a scaling
16 analysis where we look at -- we do a non-
17 dimensional analysis of the state equations that
18 would affect the building, and from that we
19 develop our non-dimensional groups as they relate
20 to the parameter of importance -- say, in this
21 case, building pressure at different times.

22 Then from that, those non-dimensional
23 groups should give you insights to your PIRT. The
24 importance of those non-dimensional groups should
25 match up with the phenomena that you have selected

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 in your PIRT. We are in the middle of that
2 scaling analysis right now. It is not finished
3 yet.

4 The other thing the scaling analysis
5 can do for you is it can look at what I would call
6 differences in aspect ratios of the test
7 facilities that you are looking at. We are going
8 to talk about some test facilities later, some
9 containment test facilities that we benchmarked,
10 and by looking at them, you will tell that they
11 don't exactly match the aspect ratios, for
12 example, of the EPR containment.

13 So from our uncertainty analysis, we
14 would identify any of those non-dimensional
15 parameters that seem to be or appear to be of
16 higher importance in the facility versus the EPR
17 containment based on its dimensional
18 characteristics.

19 You have just about exhausted
20 everything I know about how we are doing the
21 uncertainty analysis. We will be talking about
22 that.

23 CHAIRMAN POWERS: We have not exhausted
24 my questions on the uncertainty analysis.

25 MR. PARECE; Well, and we are going to

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 talk about that later, because on the uncertainty
2 analysis we also then -- of those PIRT and those
3 important parameters -- so put the scaling part
4 aside. From those important parameters, we then
5 looked at quantifying what the uncertainty might
6 be on those parameters, whether it is wall
7 condensation, material properties or whatever, and
8 then we took a statistical sampling, and we ran 49
9 cases with those variations to determine the
10 sensitivity of the pressure to those, and we are
11 going to talk about that a little bit later.

12 The requirements, of course, that we
13 are looking at: GDC 50 requires that your
14 containment be designed to handle the pressure and
15 temperature conditions following a Loss of Coolant
16 Accident, and GDC 38 requires the containment heat
17 removal system to rapidly reduce containment
18 pressure and temperature following a LOCA.

19 The way that is sub-defined is in the
20 Standard Review Plan. The Standard Review Plan
21 basically says that, if you show that your
22 pressure at 24 hours is half the peak pressure,
23 then you have demonstrated the adequacy of that
24 cooling system.

25 So those are the dominant GDC.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 So in our evaluation model development
2 program, we looked at PIRT for the containment for
3 the mass and energies. We used some existing PIRTs
4 and demonstrated their applicability to the EPR,
5 and then we had our experts look at any
6 differences between the EPR or special functions
7 or features of the EPR compared to what might have
8 been looked at in the PIRT to make sure we
9 identified any other issues. So it based on
10 specific PIRTs that exist. Next slide.

11 We also did an assessment of the -- We
12 looked at the data assessments for RELAP5, which
13 is our mass and energy code for the early blowdown
14 phase and reflood. GOTHIC -- we use GOTHIC for
15 long term M&E. So we just -- GOTHIC does the M&E
16 and the containment building internally in the
17 long term.

18 We looked at previous test data and
19 code assessments, and for the scaling we developed
20 equations for scaling analysis. So our intention
21 when our scaling analysis is complete is to
22 demonstrate that the GOTHIC benchmarks in
23 particular that we used to validate the EPR
24 response are applicable to the EPR geometry.

25 So when we went through all of this in

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 the PIRT, what we determined was that, from the
2 previous code assessments and from the PIRTs that
3 we did, that RELAP5-BW is the code we are using.
4 It is a version of RELAP5, MOD2, and it was
5 originally developed for Appendix K type
6 applications, and GOTHIC which is pretty standard
7 industry containment code now -- that they
8 predicted the medium or high ranked PIRT phenomena
9 that were important, except we had a couple of
10 notable exceptions.

11 That process we talked about with hot
12 leg injection is a multi-dimensional process, and
13 RELAP5 is a 1-D code. So RELAP5 couldn't model
14 that.

15 The other issue was interfacial heat
16 transfer between the in-containment refueling
17 water storage tank and the atmosphere. If you
18 remember the geometry, it is pretty complex down
19 there. We have a roof over the top with holes in
20 it, and the water level is down below. How wavy
21 is the water level?

22 We've got water running across the
23 floor and dumping into the holes, and it is
24 relatively hot, because that water is coming from
25 the reactor coolant system through the break, and

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 so the point was you have a lot of uncertainties
2 about any heat transfer mechanism.

3 So our approach on these two things is
4 to use conservative biases or analytical
5 treatments. In particular for the IRWST, you can
6 just turn the heat transfer off between the
7 interface heat transfer. So we did.

8 So we will talk about that later. Some
9 of these treatments we will talk about in the
10 proprietary session.

11 So in addition to all the various code
12 benchmarks that are out there for these different
13 codes, we did run some specific items from our
14 interaction with the NRC and from our own
15 approach, for our own edification.

16 So for the RELAP assessments against
17 FLECHT-SEASET data show that we have good carry
18 out from the core, a good movement of the quench
19 front during the refill or refill of the core.

20 Why that is important is that moisture
21 goes out through the broken loop and into the
22 steam generator where it gets vaporized due to the
23 secondary to primary heat transfer. So that is a
24 source of energy into the building. So we
25 validated that, and the heat transfer from

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 secondary to primary from the FLECHT-SEASET data
2 was also well predicted, and that is the second
3 piece of what I talked about.

4 So those were some additional
5 benchmarks that we performed, and then for the hot
6 leg mixing and condensation efficiency, we looked
7 at a number of tests, including cylindrical core
8 test facility, the slab core test facility, the
9 upper plenum test facility.

10 So we looked at how those facilities
11 worked, and we did some benchmarks to those tests,
12 and then we also looked at some CFD codes and what
13 they would predict for mixing, because again you
14 need a link -- In many cases, you need a link from
15 the test facility to the EPR geometry and flow
16 rates.

17 So we validated that hot leg injection
18 eventually terminates the steaming to the
19 containment, and we developed a conservative model
20 which we will discuss some details in the
21 proprietary session.

22 Then we assessed GOTHIC multi-node and
23 single-node models against a number of tests, but
24 we were very interested in two particular tests in
25 particular, HDR, Germany acronym, HeissDamph

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 Reaktor; and BFMC is Battelle-Frankfurt Model
2 Containment.

3 These were of particular interest to
4 us. GOTHIC has been evaluated against a number of
5 test facilities for a number of -- all the models
6 and phenomena, but these were important to us,
7 because they had some tests that were no sprays or
8 fan coolers, which is like our design basis, dry
9 containments, meaning that they didn't have
10 suppression pools, and then multi-compartments.

11 So that was important to us, because
12 our energy flows from one compartment to the
13 bigger compartments, and these gave us good
14 benchmark opportunities.

15 We looked at -- Many of these tests are
16 short term, but we had a few longer term tests
17 that were important to us.

18 We also looked at not just pressure and
19 temperature, but we looked at -- We have some
20 tests where we benchmarked the hydrogen
21 concentration predictions and other phenomena, but
22 today we are going to talk mostly about pressure
23 and temperature.

24 Then the other thing that is in our
25 technical report is an analysis with GASFLOW,

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 which as I said, is a Los Alamos code for modeling
2 gas transport and combustion of various gases and
3 vapors. We looked at a model of the EPR and
4 looked at response of the LOCA and the building to
5 that LOCA over a long time period.

6 The uncertainty analysis follows the
7 Code Scaling and Applicability and Uncertainty
8 approach. In that methodology, you look at the
9 range of values and look at sensitivities of your
10 parameter of interest, which in this case was
11 predominantly pressure, to a range of values that
12 bound the value of the parameter.

13 We confirmed the important parameters
14 were identified in the PIRT. So the PIRT tells
15 you what should be important. Then you do a
16 sensitivity analysis and look at a large number of
17 cases. As I said, we did a sample. We looked at
18 59 combinations.

19 When you do the analysis, it should
20 validate the PIRT. In other words, if -- You
21 shouldn't get any surprises. If you did your PIRT
22 and you are all smart guys and you know the
23 phenomena and you know the processes, then when
24 you do the uncertainty analysis, it should show
25 you that the parameters that said we were medium

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 and high are, in fact, showing up as the ones that
2 affect the sensitivity.

3 If you get something -- you know, some
4 importance that you didn't expect, then you have
5 to go back and revalidate your approach. So that
6 -- I like the way those two things work together,
7 because one is a thought exercise, and then it is
8 backed up through analytical results of the
9 uncertainties, and you try and bound the
10 uncertainties.

11 The modeling approach that we took, of
12 course, meets the regulatory requirements of
13 Standard Review Plan, and I will just reiterate
14 again for later. The codes we are using for mass
15 and energy release in the short term, we are using
16 RELAP5, and in the long term we are using GOTHIC.

17 We will discuss -- The GOTHIC model is a multi-
18 node GOTHIC model that represents the different
19 compartments of the EPR containment.

20 CHAIRMAN POWERS: You have spoken
21 extensively about validation and handling of mass
22 and energy going into the containment line break,
23 certainly a key part of the regulations.

24 You have not said anything about the
25 containment vis a vis 10 CFR Part 100 and the

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 source terminations in the containment. AT what
2 point will we discuss those?

3 MR. PARECE: I was not going to discuss
4 those today, but we can. You are being chastised
5 for not being close to the microphone.

6 CHAIRMAN POWERS: I get even right
7 after the session is over. He has to write the
8 meeting report. He may find it is difficult to
9 get it approved.

10 MR. PARECE: I was not prepared to talk
11 about the radiological part today, because --

12 CHAIRMAN POWERS: That's fine. Just
13 when we discuss that.

14 MR. PARECE: Well, I guess --

15 CHAIRMAN POWERS: The containment is
16 there for a purpose.

17 MR. PARECE: That's correct.

18 CHAIRMAN POWERS: And it is
19 radiological in nature.

20 MR. PARECE: So we are okay on time.
21 So I'll give you a preview of that. We are using
22 alternate source term methodology. So the source
23 term into the building comes entirely from that,
24 and then --

25 CHAIRMAN POWERS: I am unaware of an

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 ultimate methodology that is appropriate for this
2 plant.

3 MR. PARECE: No, we believe the
4 ultimate source term approach is appropriate, that
5 there have been approvals for other units.
6 Westinghouse doesn't have a safety related system
7 either, and they are using alternate source term.

8 So that can be presented to you at
9 another time, but we use the alternate source term
10 approach, and we made one adjustment to the design
11 in the U.S., and that is to buffer the in-
12 containment refueling storage tank solution post-
13 accident. We buffer, so that we keep the pH of
14 the liquid in the IRWST.

15 So any iodine that is entrained or
16 captured in the water that condenses and goes into
17 the IRWST, we buffer so that we can limit the
18 amount of iodine that goes back into the
19 containment atmosphere.

20 From that, we use leak rate
21 assumptions, and again all of our leakage, no
22 matter where, is filtered by safety related
23 systems. So we did our dose calculations for both
24 the control room and for off-site dose to the
25 public using that approach.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 I will say, we made some adjustments to
2 intakes to the control room to move them away from
3 -- those receptors away from possible sources of
4 emission during an event. In other words, the
5 stack. We treat the stack as a ground level
6 release, even though it is elevated, but we move
7 the intakes away from the stack, and we made some
8 adjustments on dampers and what-not.

9 The source term in the United States
10 using rules according to alternate source term is
11 generally 4,000 times greater than what is used in
12 the IAEA approach in Europe. So we had to make
13 some adjustments to accommodate that.

14 MS. SLOAN: Well, Marty, I would also
15 add that we are on the schedule for next July to
16 talk about Chapter 15, and Chapter 15 does address
17 radiological dose consequences. So you asked
18 when. That is what is currently on the schedule,
19 unless you wanted a discussion earlier than that
20 of that particular topic.

21 CHAIRMAN POWERS: What I am concerned
22 about is that what is conservative for thermal
23 hydraulics may not be conservative for source
24 terms. In fact, it can be absolutely inverse to
25 each other. So I get nervous when we start

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 talking that this is conservative, because it is
2 conservative in a context.

3 The context here, of course, is thermal
4 hydraulics and pressurization and heat loads. It
5 may not be conservative for source term
6 considerations.

7 It is unfortunate that things are
8 separated as much temporally as they are. But we
9 will live with it. But I understand, we will come
10 back to what is claimed to be conservative here
11 when we get to the source term issue.

12 MR. PARECE: And I would expect that,
13 and a source term is done specifically according
14 to the rules of that methodology. So they have
15 long been disconnected.

16 So we take that as a note, and you will
17 get your chance to review that and discuss that in
18 that other meeting.

19 So this slide here is just kind of an
20 overview of our prediction of a sample cold leg
21 pump suction break and the prediction by our
22 evaluation model of that break, compared with the
23 best estimate plus uncertainty analysis we did for
24 the CSAU methodology.

25 So this shows all 59 cases, if various

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 parameters, and whenever possible we did double-
2 sided sampling. So if there is a parameter that
3 has plus or minus 10 percent, then that was the
4 sampling range. Some parameters, we might not be
5 able to do double-sided, but we would do then
6 either a conservative approach for that one
7 parameter and just leave it that way or do a
8 single-sided sample, either of nominal or the
9 worst case.

10 This shows the 59 cases all plotted
11 together, and from this we gleaned certain
12 information from this. And in the nature of the
13 best estimate analysis, as we will discuss later,
14 this analysis includes best estimate M&E model,
15 mass and energy model, versus a conservative M&E
16 model and has best estimate to K heat in it, and
17 then a number of sample parameters.

18 This just generally shows the margin
19 inherent in the approach for the evaluation model.

20 MEMBER STACK: One problem I had with
21 this, it was sort of an apple and orange
22 comparison, because you did a multi-node model for
23 the evaluation model, and you did a single-volume
24 calculation for the best estimate.

25 Have you ever done a single-volume

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 calculation with the input variables for the
2 evaluation model?

3 MR. PARECE: Yes, we have. What you've
4 seen here is a delay in the approaches. As we
5 will discuss later, our original approach was to
6 use a single-node model and justify that, because
7 it becomes a one-room containment, that a single-
8 node model is appropriate.

9 Over time and working with the NRC,
10 what we determined was that the questions arose on
11 whether in the long term, as you get out to 20 and
12 24 hours, whether the single-node model was still
13 adequate, because with a single-node model, by
14 definition, you are assuming perfectly good
15 natural convection and all the surfaces see the
16 vapor.

17 So in that process, we switched to a
18 multi-node model, and we do agree that the multi-
19 node model gave better accuracy. So in the E&M we
20 switched to the multi-node model. But based on
21 the results that we had and the mixing results we
22 will talk about later, we didn't feel compelled to
23 redo all the uncertainty calculations with a
24 multi-node model, because of the results --

25 MEMBER SHACK: Just do the evaluation

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 model with a single-node and -- You know, if you
2 convince me that it doesn't change at all that
3 much, then I will believe this comparison, but at
4 the moment --

5 MR. PARECE: In general, the single-
6 node model -- A single-node model over-predicts
7 the blowdown peak a little bit, but in the long
8 term it will under-predict the long term pressure
9 by a little bit. And we will show a benchmark
10 later.

11 MEMBER SHACK: The other thing that
12 struck me as peculiar is that you did the switch
13 at somewhere between 1,000 and 1200 seconds. I am
14 not quite sure just where it was done in these
15 particular calculations from RELAP to GOTHIC.

16 MR. PARECE: We will discuss those
17 details in the next session. So write that down,
18 and save that question. We are going to cover
19 that.

20 MEMBER SHACK: Well, this diagram only
21 appeared in this presentation.

22 MR. PARECE: This one? I'm hoping I
23 have this diagram in the next one, too.

24 MEMBER SHACK: Got it in the next one,
25 too? Okay. I missed it when I flipped through.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 MR. PARECE: Okay. Good. So I believe
2 this is the end of the open session. Right? This
3 is the last slide.

4 MEMBER RAY: Are the initial conditions
5 for these analyses declared to be what I will call
6 your nominal two volume temperature distribution,
7 two rooms in the containment? In other words, is
8 that a limiting condition for operation or can you
9 operate the plant with loss, let's say, of cooling
10 of the plant?

11 MR. PARECE: The answer to that
12 question is right now the analyses are performed
13 with the limits for those rooms. For example, the
14 service space limit is 86 degrees Fahrenheit for
15 habitability, and the equipment space for concrete
16 production is 140, but we try and control it to
17 131. That is a metric -- you know, Celsius to
18 Fahrenheit.

19 MEMBER RAY: So habitability is, in
20 fact, a limiting condition for operation?

21 MR. PARECE: But -- But we will do some
22 assessments if there is a utility -- and there is
23 likely to be -- that they don't want instantaneous
24 access all the time, that in fact they would like
25 to run the unit and, if they think they need

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 access, they will turn on the HVAC and purge
2 everything. If that is the case, we will have to
3 run those assessments to see if there is any
4 significant effect of changing the normal
5 operating service space to, say, 90 or 95 degrees.

6 MEMBER RAY: Okay, but for design
7 certification purposes at this point in time, I
8 assume that, even though the cooling in that space
9 isn't safety related, it does constitute a
10 limiting condition for operation. Correct?

11 MR. PARECE: Right. So if during
12 operation the temperature started to rise because
13 there is some problem with the HVAC system, they
14 would have to go into those service spaces and see
15 what is going on with the fans or the chillers.
16 But the good thing is the compressors and all that
17 for the operational chilled water system are
18 outside the building.

19 MEMBER RAY: Yes, sure. No, I
20 understand. I just want to be clear in my mind
21 that these do constitute limiting conditions to
22 operations.

23 MR. PARECE: Right. And then there is
24 one advantage you get from having a shield
25 building around the containment, and that is that

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 the radiation heating that you get, especially in
2 the summertime at plants in the U.S., doesn't
3 exist. The sunshine and the outside air
4 temperatures are on the shield building, not on
5 the containment. So we've got that going for us.

6 CHAIRMAN POWERS: Are there any other
7 questions from Members on this presentation? We
8 will be plunging further into the details in the
9 next session.

10 In that case, we will take a break
11 until 25 after the hour.

12 (Whereupon, the foregoing matter
13 proceeded to Closed Session at 10:32 a.m.)

14 - - -

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

A F T E R N O O N S E S S I O N

Time: 1:14 p.m.

CHAIRMAN POWERS: It is time to come back into session. I will remind the members of the Subcommittee that Derek has to give a summary to the full ACRS. So at the end of the meeting, I will ask you for input to Derek's summary that he is giving to the ACRS.

I may have overlooked mentioning that to him.

We are ready to go back into an open session now, overview of US EPR Analysis Methodologies, and Mr. Salm will lead us through this.

MR. SALM: Yes, thank you. I am Bob Salm. I joined B&W in 1973, working in the LOCA Analysis Group. In the early Seventies -- well, middle Seventies, I moved to Germany and was involved in the design, licensing and start-up of Meulheim-Kaerlich Power Plant in Koblenz, and that was a B&W 205 fuel assembly plant like Bellefonte.

CHAIRMAN POWERS: Dr. Bonaca knows that plant, too.

MR. SALM: Yes. And it ran fabulously for a year. I came back to the U.S., was involved in space nuclear and a variety of DOE type nuclear

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 projects for BWXT, retired from BWXT in 2002,
2 worked as a contractor, joined AREVA in 2006.

3 I am Manager of the New Plants Process
4 Engineering Organization, which contains thermal
5 hydraulic analysis, LOCA analysis, non-LOCA,
6 radiological, PRA and severe accident. So it does
7 most of the analytical -- process analytical work.

8 I am here to talk about the safety
9 analysis methodologies, and I will start off by
10 presenting the features of the US EPR that are
11 relevant to safety analysis, then talk a little
12 bit about the AREVA methodologies, their
13 applicability to the EPR, and then in a closed
14 session we have picked out three specific
15 methodologies to talk about in more detail , rod
16 ejection, realistic large break LOCA methodology
17 and small break LOCA methodology.

18 Jonathan Witter is an advisory engineer
19 in the fuels analysis organization, and he is our
20 expert on the fuel methodologies, and he will be
21 talking about the rod ejection methodology. Next
22 slide.

23 Just as a point of orientation, this is
24 a four-loop PWR, very similar to the Westinghouse
25 four-loop plants. The volumes of the primary

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 system have been scaled up in proportion to the
2 power. The flow areas have been adjusted to have
3 the same velocities, the pressurizer a little bit
4 larger, the secondary side is a little bit larger
5 to give the operator a little more time to
6 respond. But basically, it is a scaled-up four-
7 loop PWR.

8 A couple of things to notice on this.
9 I will try Marty's laser. We've got the hot legs
10 are grouped together, and the cold legs are
11 grouped together. This provides a more compact
12 arrangement for the components, and on the hot
13 legs you have the nozzles where the RHR residual
14 heat removal system let-down lines are located.
15 Those are the same nozzles where we inject hot leg
16 injection to suppress steaming.

17 In the cold legs we have the
18 accumulator line nozzles that also are used to
19 inject the low head safety injection and medium
20 head safety injection. Next slide, please.

21 This is a side view of the plant
22 showing the elevations, and in particular, what I
23 wanted to point out is the relationship between
24 the top of the cold leg and the top of the core
25 and the loop seal, and the top -- the cold leg

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 cross-over pipe is 30 millimeters below the top of
2 the core.

3 So it is a shallow loop seal which
4 enables steam to be vented more easily. And as
5 Marty pointed out, the steam generator tubes are a
6 little bit larger, and things are done to reduce
7 the pressure drop around the loop, which also
8 promotes the venting of the steam.

9 Okay. As Marty has already told you,
10 there are four trains of accumulators, medium head
11 safety injection, low head safety injection which
12 also functions as a residual heat removal system,
13 has a heat exchanger in it, and four trains of
14 emergency feedwater, and four trains of main steam
15 relief.

16 I will tell you a little bit more about
17 the main steam relief train. It is a safety
18 grade system. It is comprised of two valves in
19 series. One is a control valve, and the other is
20 an isolation valve. When the plant is operating,
21 the control valve is open, and the isolation valve
22 is closed.

23 The isolation valve is opened on SI
24 signal. It also opened to respond to like a
25 turbine trip where you pressurize the secondary

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 side. It has a capacity of 50 percent of the
2 steam flow, and it has a nominal setpoint of 1385
3 psia.

4 There are two main steam safety valves,
5 each with 25 percent capacity, and those have
6 setpoint of 1475 psia. So they are quite a bit
7 higher, and for virtually all events the main
8 steam relief train is able to mitigate the event
9 without challenging the safety valves.

10 When you get an SI signal, setpoints of
11 the control valve for the main steam relief train
12 are ramped down in pressure at a predetermined
13 rate corresponding to 180 degrees per hour from
14 the 1385 psi down to 870 psi, which takes about 20
15 minutes. This is preprogrammed and has nothing to
16 do with the actual response of the primary system
17 or secondary system. It just a change in the
18 setpoints.

19 After the partial cooldown is complete
20 at 180 degrees per hour, the operator is able to
21 initiate a 90 degree per hour cooldown, and that
22 is generally assumed in our analyses. As Marty
23 has told you earlier, part of the design of the
24 plant is that no operator actions are credited in
25 the first 30 minutes of the event.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 There is another mode for the main
2 steam relief train. If there would be a tube
3 rupture, a setpoint of the main steam relief train
4 can be raised to 1436 psi, which is high enough so
5 it is above the cutoff head of the medium head
6 safety injection.

7 This way, the medium head safety
8 injection can't open the valves and cause a
9 discharge outside of the containment.

10 MEMBER STETKAR: Does that happen only
11 on the ruptured loop, or do you raise them all
12 four?

13 MR. SALM: Only in the affected one.

14 MEMBER STETKAR: You don't want to blow
15 down the other three.

16 MR. SALM: Correct. And there is an
17 automatic actuation. If you have completed the
18 automatic partial cooldown and it detects a high
19 level on one of the steam generators, it will
20 reset that main steam relief train based on that
21 high level.

22 The operator can also do it. There is
23 radiation monitors in the blowdown line and in the
24 main steam line. So if the operator detects
25 activity, he, too, can raise the setpoint.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 All right. I guess we are turning to
2 our slide up here. The LHSI are cross-connected,
3 two by two, between adjoining loops, and these
4 cross-connects are opened when any train of LHSI
5 is removed from service for preventive
6 maintenance; and as Marty said, this is to ensure
7 an even distribution of liquid around the
8 downcomer, so it doesn't get entrained out a
9 broken leg.

10 Let's see. The design also includes an
11 automatic reactor coolant pump trip. This occurs
12 on an SI signal and low DP across the pump. The
13 reason the DP signal is there is to differentiate
14 between a small break, maybe a tube rupture where
15 you would want the reactor coolant pumps to
16 continue to operate, and a larger LOCA where you
17 get two-phase conditions and the pump starts to
18 degrade. That is automatic.

19 The design has low DNBR and high when
20 your power density trips in containment.
21 Refilling water storage tank -- Marty talked about
22 that, and besides being the source of water for
23 the MHSI and LHSI, it also obviates the need for
24 having a switchover to the sump at some point
25 during an event.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 CHAIRMAN POWERS: You are going to have
2 to remind me. Sandra failed me -- all her fault.
3 She promised her crib notes over here. It does
4 not have her this LPD RT. Tell me that acronym.
5 It's all Sandra's fault. Blame her.

6 MR. SALM: All right. I'm sorry.

7 CHAIRMAN POWERS: LPD RT is?

8 MR. SALM: Reactor trip.

9 CHAIRMAN POWERS: RT is the reactor
10 trip. LPD is?

11 MR. SALM: Low power density.

12 CHAIRMAN POWERS: Low power density.

13 MR. SALM: Linear power density. I'm
14 sorry.

15 CHAIRMAN POWERS: Ah, we don't even
16 know what this is. No wonder Sandra didn't
17 include it. Too much argument.

18 MR. SALM: No, I'm in the safety
19 analysis. This is fuel. They don't let us use
20 it.

21 The design also has an extra borating
22 system. This is a system that injects very high
23 concentrated boron.

24 CHAIRMAN POWERS: Can you tell me -- I
25 was going to ask. How high is the boron

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 concentration in this?

2 MR. SALM: I don't know. Does anybody
3 here know? Marty, do you know?

4 CHAIRMAN POWERS: There is a limit. It
5 is going to saturate sooner or later.

6 MEMBER STETKAR: Well, the key is how
7 big is the pump?

8 MR. PARECE: This is Marty Parece. The
9 extra borating system contains a boron
10 concentration in the tanks of 7,700 parts per
11 million, and that is enriched B-10. So it is
12 equivalent of natural boron of 12,000 ppm, and the
13 pumps are positive displacement pumps, and each
14 pump is about 44 gallons per minute. But it does
15 allow you to put in approximately one percent DK
16 over K in about 20 minutes.

17 MEMBER STETKAR: But it is not an ATWS
18 mitigation. It is a positive hold-down type.

19 MR. PARECE: Right. So without
20 stealing Bob's thunder, what it allows you to do
21 is allows you to add boron to the plant. So you
22 can reach cold shutdown using a safety grade
23 system from the control room, even with a loss of
24 off-site power and a single failure.

25 MR. SALM: Thank you, Marty. Okay, a

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 couple of other design features I just want to
2 mention: The steam generators have an axial
3 economizer in them. What this is, there is a
4 separator plate that comes about halfway up the
5 tube bundle that separates the hot leg side from
6 the cold leg side, and on the cold leg side there
7 is a double wrapper that functions as a downcomer
8 that channels the main feedwater to one side of
9 the bundle.

10 It is open on the top. There is
11 recirculation, but there is only about 10 percent
12 recirculation on that side and about 90 percent
13 recirculation on the hot side. This allows you to
14 bring your cold leg temperatures down.

15 The design has a heavy reflector in the
16 vessel. It has a 14 foot core, active core, and -
17 - let's see, what else? I think I have talked
18 about everything. Next slide. Any questions
19 about any of those systems?

20 MEMBER STETKAR: Yes, only because I
21 haven't read enough yet. In the IRWST suction for
22 the MHSI and LHSI pumps, there is what looks like
23 a three-way MOV. Is it really a three-way MOV?
24 Both pumps take suction at the same time?

25 MR. SALM: I don't know. Marty, would

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 you know?

2 MEMBER STETKAR: One valve only blocks
3 the IRWST suction to both pumps. Right?

4 MEMBER RAY: I have been trying to
5 think through the four times 100 principle that
6 Marty explained, long term out of service for one
7 and then normal tech specs on what would then be
8 the remaining three. That wouldn't apply, or does
9 it, to the main steam relief train, because I am
10 just trying to think about it as each leg serves
11 just one steam generator.

12 So any out-of-service time on a main
13 steam train is going to remove 25 percent of your
14 blowdown capability on the secondary side. Does
15 it work the same way in terms of requirements for
16 operability of that train, each train? Involve a
17 safety analysis assumption -- is that right?

18 MR. PARECE: To answer that question,
19 the main steam relief trains don't normally need
20 maintenance on line. So the main provision for
21 the main steam relief train is that they are
22 operable during operation.

23 I believe that in our analysis we have
24 assessed the effect of having either main steam
25 relief trains available for over-pressure

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 protection or safety valves available for over-
2 pressure protection, and not both at the same
3 time. However, generally, you would have to have
4 those operable.

5 So when you take a division out of
6 service, we do take all the big movers out of
7 service and the emergency diesel and part of the
8 HVAC systems out of service, but those main steam
9 relief trains remain operable, because they are on
10 a powered bus, and if we lose off-site power, they
11 are battery backed for two hours.

12 So you have the use of them, even in a
13 loss of off-site-- a total loss of power to that
14 division. You have the use of those relief trains
15 for at least two hours.

16 MEMBER RAY: Okay, but still the answer
17 remains, you are relying on all four, subject to
18 some inoperability, but limited in time.

19 MR. PARECE: Correct.

20 MR. SALM There are scenarios where we
21 assume that the failures of the MSRT either to
22 open or to close.

23 MEMBER RAY: You have to take one train
24 out of service to do surveillance testing, for
25 example. I'm sure you must have some kind of

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 online surveillance of the actuation system.

2 MR. PARECE: The surveillance testing
3 for that system is done separately. It is powered
4 by solenoids valves that are powered from
5 different divisions that -- or pilot valves that
6 equalize the pressure across the main valve.

7 So we do surveillance on each one of
8 those, and it is out of service for such a short
9 time that it is governed by the AOT.

10 MEMBER RAY: Right. That is all I was
11 saying.

12 MR. SALM: Any other questions? All
13 right.

14 This next slide shows the pressure,
15 primary system and secondary system pressure
16 response for a spectrum of LOCA. On the lefthand
17 side there's bars that show the degraded heads of
18 the MHSI, the accumulators and the LHSI. So you
19 can see where they are going to discharge.

20 We look at the secondary side pressure.
21 That is the dark blue line. Pressure starts out
22 1120-1130 psi range. When there is reactor scram,
23 typically we assume turbine trip, and it closes
24 off the secondary side. We don't take credit for
25 the main steam bypass.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 So the secondary side pressure rises
2 quickly to the normal setpoint for the MSRT. It
3 stays there until you get an SI signal. When you
4 get an SI signal, it starts the automatic
5 depressurization at 180 degrees per hour until it
6 gets down to 870 psi where it holds the pressure
7 until the operator initiates a 90 degree per hour
8 cooldown.

9 We look at the primary system response.
10 If we start out with a double-ended guillotine
11 break, it is large enough that it quickly
12 depressurizes the primary system down to low
13 pressure. No surprise there.

14 As the break gets smaller, the rate of
15 depressurization decreases. If we look at the
16 four-inch break, that is roughly the size of a
17 break that is capable of depressurizing the
18 primary system without the secondary side.

19 If you get above that -- or excuse me,
20 smaller than that break size, then the break is
21 too small to depressurize the primary system. It
22 relies on the secondary side to provide some
23 amount of energy removal, and so the primary
24 system gets pulled down by the secondary side as
25 it is depressurized.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 If you have a smaller break, such as a
2 one-inch break, now the capacity of the MHSI is
3 sufficient to hold the primary system pressure up,
4 even though the temperature of the primary system
5 is being brought down with the secondary side.
6 Questions? Next, please.

7 Okay. Talk a little bit about the
8 methodologies, starting out with the non-LOCA
9 methodology.

10 The AREVA methodology is defined in
11 EMF-2310. That was approved in 2004. The
12 methodology used for the EPR is very similar to
13 that except that the COPENIC code has replaced
14 the RODEX2 code. COPENIC is a newer code.

15 We use S-RELAP5, which is a derivative
16 of our RELAP5 MOD2.5, for the primary system
17 response. We use LYNXT, which is a derivative of
18 COBRA, for doing the core analysis DNB, and for
19 the EPR we use the in-core trip, and there has
20 been a special methodology developed for that.
21 That is currently being reviewed by the NRC.

22 The main steam line break is a special
23 methodology, and I will talk a little bit more
24 about that later on.

25 Then rod ejection, Jonathan is going to

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 talk about later on in the closed session. It is
2 a revised methodology. It was revised to
3 implement the guidance of SRP 4.2. It couples the
4 neutronics and hydraulic to predict the core
5 response and, again, there is a topical report
6 that is being reviewed by the NRC right now on
7 that, and Jonathan will talk more about that. Next
8 page.

9 As you heard already, we use a
10 realistic statistical methodology for evaluation
11 large break LOCA. This is the Realistic LOCA
12 methodology. that uses RODEX3A to do the fuel
13 analysis, S-RELAP5 to do the plant analysis. It
14 has ICECON, which is a derivative of CONTEMPT, to
15 do the concurrent containment analysis. They are
16 explicitly coupled, and that methodology is
17 described in EMF-2103, which was approved in 2003.

18 Small break LOCA methodology is a
19 deterministic Appendix K methodology. It uses
20 RODEX2. Portions of the RODEX2 code were
21 incorporated in S-RELAP5, so it could do the hot
22 pin calculation during the plant analysis, and
23 that is described in EMF-2328, which was approved
24 in 2001. Next slide.

25 Fuel analysis methodologies -- this is

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

Jonathan's area: That is described in EMF-96029, which was approved in 1997. It uses MICBURN/CASMO-PRISM, and I will let him answer any questions about that. And NEMO-K for the kinetics uses COPERNIC for the fuel responses and LYNXT for the core hydraulics and DNB.

Any questions? I will talk more about that in the closed session.

All right. Next page. These methodologies have been used for a variety of operating plants. You can see the list. They are little changed for EPR.

MEMBER MAYNARD: A question: These have been approved for other applications. You are doing the work now to show the applicability for the US EPR.

MR. SALM: Correct.

MEMBER MAYNARD: Is that being done within the DCD review or are you submitting separate topical reports?

MR. SALM: In most cases, we have submitted separate topical reports, and some of them have already been approved. Some of them are still being reviewed, and it is really going concurrently with the FSAR review.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 MEMBER MAYNARD: Okay. This is
2 something for the Committee. If the topical
3 reports are being reviewed by the staff, unless we
4 ask for them, we may or may not see those reports
5 before we are asked to make a decision on the EPR
6 from the DCD reviews.

7 MS. SLOAN: Just to be specific, we
8 submitted a code applicability topical report
9 addressing non-LOCA and small break LOCA, and that
10 has been approved and an SER has already been
11 issued by the staff, and the RLBLOCA topical
12 report for application to EPR is currently under
13 review by the staff as part of the design
14 certification.

15 MR. SALM: Next slide. This slides
16 shows the reports. The first one, ANP-10263,
17 shows the applicability for the non-LOCA events
18 and the fuel codes. 10278 is the applicability of
19 the Realistic LOCA methodology, and there is a
20 supplement, ANP-10291, that provides more
21 information on the small break methodology.

22 The first one has been approved. The
23 second one is being reviewed right now, and the
24 third one is actually just a technical report to
25 support the FSAR.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 These reports take each event, and in
2 many cases each phase of the event, and describe
3 it, identify the important phenomena, identify the
4 important components and functionality during that
5 phase of the event, and provide an assessment of
6 why these methodologies are applicable to the EPR
7 and why the methodologies can be used. So it
8 breaks it down in detail, phase by phase.

9 In the closed session, we will see more
10 of what is reviewed in these topical and technical
11 reports. Next page.

12 So really in summary, the AREVA
13 methodologies are mature. The rod ejection
14 methodology was updated to address a change in the
15 SRP, but these are mature methodologies that have
16 been applied for years to operating plants.

17 The EPR design, while it has some
18 special features, is basically a four-loop PWR.
19 It is very similar in operating conditions. It
20 has the same phenomena, and the events, the
21 phenomena, remain in the range of applicability
22 for the constituent of models that are already
23 used in the codes.

24 So the methodologies are applicable to
25 the EPR where --

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 CHAIRMAN POWERS: You say it has the
2 same phenomenon methodology -- I mean it has the
3 same phenomena as occurring in a four-loop PWR.
4 How do you know that?

5 MR. SALM: Well, I mean in the topical
6 reports we go down in each phase --

7 CHAIRMAN POWERS: That says the code
8 thinks it has the same phenomena.

9 MR. SALM: We will talk more about that
10 in the closed session, you know, be more specific
11 about which phenomena and which components.

12 CHAIRMAN POWERS: But we don't really
13 have any experimental verification of your
14 statement.

15 MR. SALM: Well, we have the
16 experiments that have been used to validate the
17 methods for operating plants, and where there is
18 unique phenomena like the hot leg injection, we
19 have gone back to the tests and looked
20 specifically for those phenomena and justified the
21 methodologies. But certainly, most of what is
22 going to occur for this plant would be exactly the
23 same as for current plants.

24 CHAIRMAN POWERS: I am just trying to
25 understand why you think that is true.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 MR. SALM: Well, we've looked at the
2 differences in the design. We look at the tests
3 and use engineering judgment. In the closed
4 session, we will talk a little bit more about the
5 level of detail that we went to.

6 When we run the analyses, it produces
7 the results that one would expect. There aren't
8 any surprises.

9 CHAIRMAN POWERS: It's just the code
10 thing. I mean, if something happens between 4400
11 megawatts thermal and 4500 megawatts thermal that
12 changes some physics computer code, you will never
13 know about it unless you put it in.

14 MR. SALM: Well, I mean, how do you
15 mean that? that it doesn't have the degree of
16 resolution to --

17 CHAIRMAN POWERS: If there is a new
18 physical phenomenon that shows up. The fuel guys
19 know about this, because between 40 gigawatt days
20 per ton and 65 gigawatt days per ton, a rim shows
21 up. The fuel codes never predicted that. They do
22 now, but they didn't.

23 MR. WITTER: This is Jonathan Witter.
24 I think one response to kind of gain some
25 confidence is the fact that the plant is really

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

1 not all that different. If you look at the linear
2 heat rates of the fuel rods, look at the core, the
3 power-up scaling of the plant aspects of the
4 computer codes that are general in nature of their
5 fundamental basis, and as Bob mentioned, looking
6 back at the test data and making sure that it does
7 make sense that the scaling aspects of the plant
8 relative to --

9 CHAIRMAN POWERS: We said the same
10 thing about the fuel codes when we went from 17 to
11 34, when we were at 34 to 40. We said it again
12 from 40 to 60 -- ah, all the physics is in there,
13 and we don't need to worry. And new physics
14 appeared. Now we are smarter, and we say it about
15 going from 60 to 75, and we are just as wrong
16 there as we were back at 17.

17 MR. WITTER: Well, I guess I don't
18 really know exactly how to respond.

19 CHAIRMAN POWERS: Well, there is no
20 real response. Until you've done an experiment,
21 there is really never a response to that question.

22 MR. SALM: All right. Well, that is
23 all I have for the open session.

24 CHAIRMAN POWERS: Okay. We are going
25 to switch over into closed session.

Presentation to the ACRS Subcommittee

AREVA EPR Design Certification Application Review Status

Getachew Tesfaye
Project Manager

September 9, 2009

Review Schedule

Task	Target Date
Phase 1 - Preliminary Safety Evaluation Report (SER) and Request for Additional Information (RAI)	Completed
Phase 2 - SER with Open Items	June 30, 2010
Phase 3 – Advisory Committee on Reactor Safeguards (ACRS) Review of SER with Open Items	September 28, 2010
Phase 4 - Advanced SER with No Open Items	April 2011
Phase 5 - ACRS Review of Advanced SER with No Open Items	July 2011
Phase 6 – Final SER with No Open Items	September 2011
Rulemaking	February 2012

Phase 3 Review Plan

<u>November 2009</u>	<u>February 2010</u>	<u>May 2010</u>
<u>Group 1</u> (2-days - 11/18 & 19) AREVA Intro Chap 2 – Site Characteristics (6/9/09) Chap 8 – Electric Power (6/16/09) Chap 10 – Steam and Power Conversion (8/24/09) Chap 12 – Radiation Protection (7/23/09)	<u>Group 2A</u> (2 days - 02/02 & 03) Chap 4 – Reactor (11/9/09) Chap 5 – Reactor Coolant and Connected Systems (10/26/09) Chap 16 – Tech Specs (11/25/09) Chap 17 – Quality Assurance (9/11/09) <u>March 2010</u> <u>Group 2B</u> (2 days) Chap 11 – Radwaste Management (7/13/09) Chap 19 – Severe Accidents / PRA (9/11/09)	<u>Group 3 (2 days)</u> Chap 3 – Design of Structures, Components and Equipment (3/25/10) Chap 7 – I & C Systems (3/25/10) Chap 9 – Auxiliary Systems (11/9/09) Chap 18 – Human Factors (8/13/09)

U.S. EPR Containment Design and Analysis and U.S. EPR Analysis Methodologies

U.S. EPR Subcommittee

Advisory Committee on Reactor Safeguards (ACRS)

9 September 2009

EPR is a trademark of the AREVA Group.

Presentation Goal

To provide background information on two key topic areas to support ACRS review of the Safety Evaluation Report for the U.S. EPR design certification application

Presentation Topics

► U.S. EPR containment design and analysis

◆ OPEN session

- Overview of containment features
- Review of containment response to postulated pipe ruptures
- Analytical methodology summary

◆ CLOSED session

- EMDAP
- Evaluation model
- Mass and energy release (RELAP5-BW)
- Containment pressure and temperature (GOTHIC)
- Benchmarks
- Limiting large break loss-of-coolant accident results

Presentation Topics

► U.S. EPR analysis methodologies

◆ Focus on safety analysis methodologies

◆ OPEN session

- Design overview
- Selection of methodologies
- Overview of non-LOCA methodology
- Overview of Main Steam Line Break methodology
- Overview of fuel analysis methodologies

◆ CLOSED session

- Control Rod Ejection
- Large Break LOCA
- Small Break LOCA

Acronymns

Acronym	Description	Acronym	Description
ACCU		ERW	Ejected Rod Worth
AMS	Aeroball Measurement System	FOP	Fraction of Power
BC	Boundary Conditions	$F_{\Delta H}$	Maximum Relative Rod Power, Axially Integrated Enthalpy Rise
BFMC	Battelle-Frankfurt Model Containment	F_Q	Peak Relative pellet Power
BOC	Beginning of cycle	F_Z	Maximum Relative Axial Power Shape Peaking Factor
CCFL	Counter Current Flow Limit	HDR	HeissDampf Reaktor
CCTF	Cylindrical Core Test Facility	HFP	Hot Full Power
CFD	Computational Fluid Dynamics	HZP	Hot Zero Power
CHF	Critical Heat Flux	IRWST	In-Containment Refueling Water Storage Tank
CSAU	Code Scaling, Applicability, and Uncertainty	ISP	
CVCS	Chemical and Volume Control System	LCO	Limiting Conditions for Operation
DC	Design Certification	LOOP	Loss of Offsite Power
DCD	Design Control document	MHSI	Medium Head Safety Injection
(M)DNB(R)	(Minimum) Departure for Nucleate Boiling (Ratio)	MSRT	Main Steam Relief Train
DTC	Doppler Temperature Coefficient of Reactivity	MSSV	Main Steam Safety Valve
EBS	Extra Borating System	MTC	Moderator Temperature Coefficient of Reactivity
ECC(S)	Emergency Core Cooling (System)	NSSS	Nuclear Steam Supply System
EDG	Emergency Diesel Generator	PCM	Percent Milli-rho of Reactivity ($10^{-5} \Delta\rho/\rho$)
EFW(S)	Emergency Feedwater (System)	PCMI	Pellete Clad Mechanical Interaction
EM	Evaluation Model	PCT	Peak Clad Temperature
EMDAP	Evaluation Model Development and Assessment Process	PIRT	Phenomena Identification and Ranking Table
EOC	End of Cycle	PWR	Pressurized Water Reactor
EPR	Evolutionary Power Reactor		

Acronyms (Continued)

Acronym	Description
RCP	Reactor Coolant Pump
RCSL	Reactor Control Surveillance Limitation
REA	Rod Ejection Accident
RHR(S)	Residual Heat Removal (System)
RIA	Reactivity Initiated Accident
SAFDL	Specified Acceptable Fuel Design Limit
SAHRS	Severe Accident Heat Removal System
SCTF	Slab Core Test Facility
SRP	Standard Review Plan
TFGR	Transient Fission Gas Release
T-H	Thermal Hydraulic
UPTF	Upper Plenum Test Facility

U.S. EPR Containment Design and Analysis

U.S. EPR Subcommittee
Advisory Committee on Reactor Safeguards (ACRS)
9 September 2009

EPR is a trademark of the AREVA Group.

Agenda

- ▶ **Containment Design Overview**
 - ◆ Specific Features
 - ◆ Response to Postulated Pipe Ruptures
 - ◆ Layout
- ▶ **Summary of Evaluation Methodology**

U.S. EPR™ Containment Design and Analysis

Martin V. Parece
Vice President, Technology
Rockville, MD
September 9, 2009

EPR is a trademark of the AREVA Group.

Agenda

▶ Containment Design Overview

- ◆ Specific Features
- ◆ Response to Postulated Pipe Ruptures
- ◆ Layout

▶ Summary of Evaluation Methodology

----- Begin Proprietary Session -----

▶ Mass & Energy Methodology

- ◆ RELAP5/MOD2-B&W transition to GOTHIC
- ◆ Hot leg injection
- ◆ Benchmarks

▶ Containment Modeling & Analysis

- ◆ GOTHIC model objective
- ◆ Benchmarks

▶ Sample Problem

EPR Reactor Building

- ▶ Post-tensioned concrete containment with steel liner
- ▶ Shield Bldg wall reinforced concrete
- ▶ Containment Free Volume = 2.8 Mft³
- ▶ Containment Inside Diameter = 153.5 ft.
- ▶ Containment Wall Thickness = 4.3 ft.
- ▶ Design pressure = 62 psig
- ▶ In-Containment Refueling Water Storage Tank (~500,000 gal)
- ▶ Design leak-rate at design pressure is less than 0.25 percent by volume
- ▶ Two-zone containment
- ▶ CONVECT system of rupture and convection foils and dampers connect zones during LOCA
- ▶ Passive hydrogen reduction system
- ▶ Severe accident mitigation features

CONVECT System – Main Components

► Level +31.40 m: Atmosphere Release Section

- ◆ Convection Foils in the Pressure Equalization Ceiling
- ◆ Rupture Foils in the Pressure Equalization Ceiling

► Level -2.30 m: Atmosphere Inlet Section

- ◆ Hydrogen Mixing Dampers

Convection Foil

Installed Convection Foil (Standby)

Convection Foil

► *Opening Characteristics:*

- ◆ Acts like a rupture foil for high pressure
- ◆ Elevated temperature opening
- ◆ No debris generation
- ◆ Bi-directional (on pressure)

CONVECT System

► Performance

- ◆ Large breaks: all foils and dampers open
- ◆ Smaller breaks: mixing relies essentially on convection foils. MAAP4 analyses addressing 10 CFR 50.44 show good mixing
- ◆ No debris generated

► Component qualification and testing

- ◆ Foils and Dampers provide redundancy and meet single failure criterion
- ◆ Designed to meet Seismic I requirements
- ◆ Part of EQ, Inspection, and Testing program
- ◆ Qualification program to show proof of concept

U.S. EPR Containment Design and Concept

- Containment pressure mitigation after a LOCA or SLB

Steam condenses on the structures and returns to IRWST

» Short term pressure peak is limited

LHSI/RHR HX removes heat

» Long term pressure is controlled

Foils & Dampers opening allow steam convection

U.S. EPR Containment Design and Concept

► Long Term suppression of steaming

- ◆ Steam line break: Steam generator feed is manually isolated
- ◆ LOCA: manual LHSI switch to hot leg injection at 60 minutes

- ◆ As a back-up, non-safety related containment spray can also be used to condense the steam

Reactor Building Vertical Section

Reactor Building -13 Ft. Section

Reactor Building +3 Ft. Section

Reactor Building +15 Ft. Section

Reactor Building +44 Ft. Section

Reactor Building +61 Ft. Section

Reactor Building +100 Ft. Section

Reactor Building +3 Ft. Section

Containment Response Evaluation Methodology

- ▶ **The methodology is described in Technical Report ANP-10299P**
 - ◆ **Applies RG 1.203 framework for Evaluation Model Development and Assessment Process (EMDAP)**
 - ◆ **Describes the M&E methodology (RELAP5-BW and GOTHIC)**
 - ◆ **Demonstrates applicability of GOTHIC methodology to U.S. EPR containment design**
 - ◆ **Describes the U.S. EPR containment design, including the CONVECT system, H₂ reduction system and severe accident heat removal system**
 - ◆ **Quantifies margin provided by conservatisms in EM**

Containment Response Evaluation Methodology

► Requirements

- ◆ **GDC 50 – Requires containment be designed to accommodate the pressure and temperature conditions following a LOCA**
- ◆ **GDC 38 – Requires a containment heat removal system to rapidly reduce containment pressure and temperature following a LOCA**
 - SRP Section 6.2.1.1.A – Provides acceptance criterion that containment pressure be $\leq 50\%$ of the peak pressure within 24 hours after accident

► EMDAP Process and PIRT

- ◆ **Evaluation Model requirements are based on PIRT**
- ◆ **U.S. EPR PIRT Identifies, ranks and assesses state of knowledge the important phenomena for**
 - Mass and Energy release evaluation
 - Containment pressure evaluation
- ◆ **U.S. EPR PIRT is based on existing PIRT and U.S. EPR specific changes**

Containment Response Evaluation Methodology

► Assessment Database and Scaling

- ◆ Reviews previous test data and code assessments for RELAP5-BW and GOTHIC
- ◆ Develops equations for scalability analysis to validate the adequacy of the benchmarks performed to validate GOTHIC

► Evaluation Model Adequacy

- ◆ Assessment of RELAP5-BW and GOTHIC show that they predict medium- and high-ranked PIRT phenomena except:
 - Multi-dimensional mixing in reactor vessel during post-reflood, hot leg injection phase
 - Interfacial heat transfer to IRWST liquid
- ◆ Methodology is adjusted to compensate for code limitations (conservative biases and analytical treatments)

Containment Response Evaluation Methodology

- ▶ **Validation and Sensitivity Analysis to demonstrate the applicability of RELAP5-BW and GOTHIC given the U.S. EPR specificities**
 - ◆ **RELAP5-BW assessments against FLECHT-SEASET data**
 - Core heat transfer and liquid carryout are well predicted
 - Heat transfer from secondary to primary is well predicted
 - ◆ **Hot leg injection mixing/condensation efficiency**
 - UPTF, CCTF, and SCTF test data support significant mixing in the core
 - Conservative mixing efficiency is validated for U.S. EPR configuration through CFD analysis with STAR-CD.
 - Hot leg injection suppresses long-term steaming to containment
 - ◆ **GOTHIC single- and multi-node models are assessed against HDR and BFMC integral-effects containment tests representative of the U.S. EPR design**
 - No sprays or fan coolers
 - Multi-compartment configuration (BFMC Biblis)
 - Short-term and long-term phenomena
 - ◆ **GASFLOW 3-D CFD code with U.S. EPR model shows good atmospheric mixing and convection in containment**

Containment Response Evaluation Methodology

- ▶ **Uncertainty analysis – follows Code Scaling, Applicability and Uncertainty (CSAU) methodology**
 - ◆ Evaluates through sensitivity studies a range of values bounding the expected value of the parameter
 - ◆ Confirms the dominant phenomena identified in PIRT. Structure properties and condensation are the dominant phenomena for containment pressure
- ▶ **Modeling and Regulatory Compliance**
 - ◆ Methodology (includes codes, biases and treatments) is compliant with NUREG-0800 SRP and ANSI/ANS-56.4
 - ◆ Codes used:
 - LOCA mass and energy release rates
 - Short-term – RELAP5-BW
 - Long-term – GOTHIC
 - GOTHIC with multi-node model predicts containment pressure and temperature response

Containment Response Evaluation Methodology

► Double-ended guillotine cold leg pump suction break sample case

The Evaluation Model is conservative

U.S. EPR Analysis Methodologies

Robert Salm

Manager,

New Plants Process Engineering

September 9, 2009

EPR is a trademark of the AREVA Group.

Presentation Topics

- ▶ **Unique U.S. EPR design features important to safety analysis**
- ▶ **AREVA methodologies**
 - ◆ Codes
 - ◆ Approved topical reports
 - ◆ Examples of application to operating plants
- ▶ **Applicability to U.S. EPR**
 - ◆ Supporting topical and technical reports
- ▶ **Summary**

Proprietary Session

- ▶ **Example methodologies**
 - ◆ Rod Ejection
 - ◆ Realistic Large Break LOCA (RLBLOCA)
 - ◆ Small Break LOCA (SBLOCA)

Reactor Coolant System

- **Conventional 4-loop PWR design, proven by decades of design, licensing & operating experience**

U.S. EPR RCS Layout

U.S. EPR RCS Elevation Drawing Showing Loop Seal

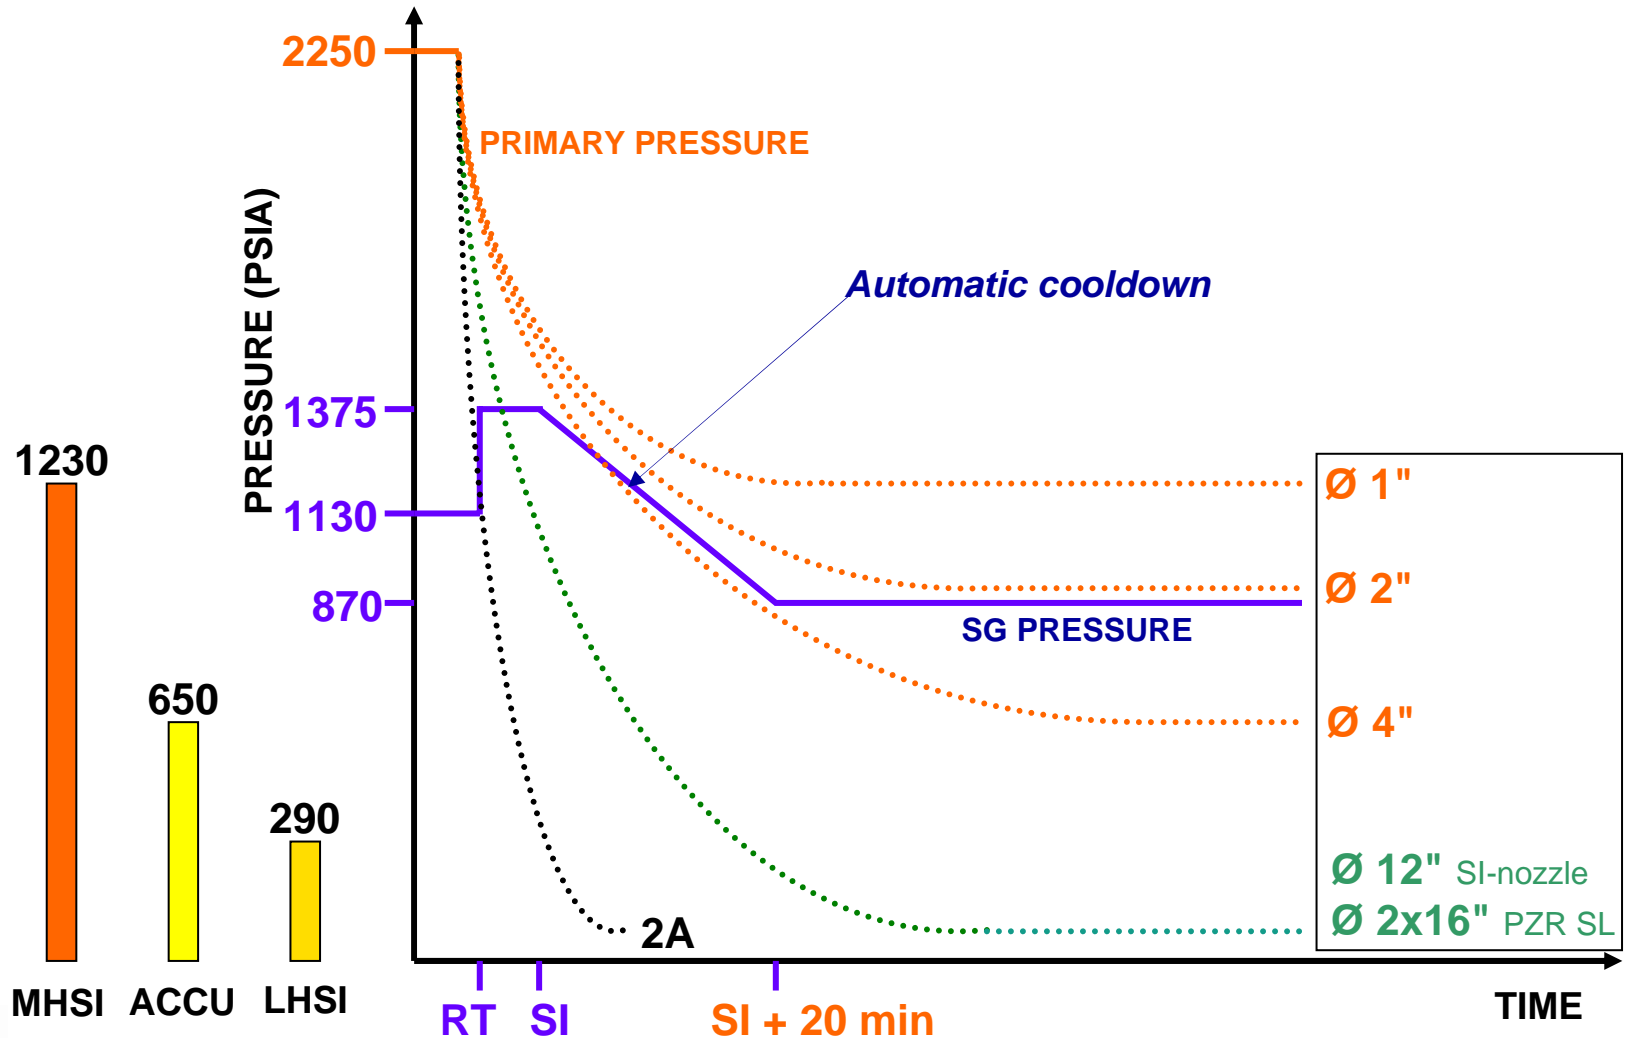

Unique U.S. EPR Safety Related Systems and Features

- ▶ Four trains of Accumulators, Medium Head Safety Injection (MHSI), Low Head Safety Injection (LHSI)/Residual Heat Removal System (RHR), Emergency Feedwater (EFW), Main Steam Relief Train (MSRT)
- ▶ LHSI cross-connects opened when one LHSI train is removed for preventive maintenance
- ▶ Four-train, safety-related system (one per SG)
- ▶ Depressurizes SGs automatically on SI signal to reduce setpoint equivalent to 180°F/hr (T_{sat})
- ▶ Automatic partial cooldown of SGs on SI signal
- ▶ Automated trip of reactor coolant pumps on coincident SI actuation signal and low DP across the pumps
- ▶ Low DNBR and High LPD RT functions utilizing in-core measurements of local core power distributions at several locations within each core quadrant
- ▶ In-Containment Refueling Water Storage Tank (IRWST)
 - ◆ Source of ECC water
 - ◆ No switchover needed
- ▶ Extra Borating System (EBS)

LOCA: RCS Pressure

Safety Analysis Methodologies

► Non-LOCA

- ◆ COPENIC replaced RODEX2 for determining initial fuel conditions
- ◆ S-RELAP5 – RCS response
- ◆ LYNXT replaced XCOBRA-IIIC for determining DNBR
- ◆ PRISM used for neutronics portion of the calculation
- ◆ “SRP Chapter 15 Non-LOCA Methodology for Pressurized Water Reactors,” EMF-2310(P)(A), Revision 1, June 16, 2004
- ◆ Applied Incore Trip Setpoint and Transient Methodologies, ANP-10287P (in NRC review)
- ◆ Main Steam Line Break methodology is a special subset of Non-LOCA

► Control rod ejection

- ◆ Implements acceptance criteria and guidance of March 2007 revision of SRP 4.2
- ◆ Manually couples neutronic, plant system, and thermal hydraulic computer codes as necessary to predict performance and any fuel failures
- ◆ “U.S. EPR Rod Ejection Accident Methodology Topical Report,” ANP-10286P, November 2007 (in NRC review)

Safety Analysis Methodologies (Continued)

► RLBLOCA

- ◆ RODEX3A – computation of the initial fuel stored energy, fission gas release, and fuel-cladding gap conductance
- ◆ S-RELAP5 – system T/H calculations
 - ICECON module used to determine containment backpressure
- ◆ “Realistic Large Break LOCA Methodology for Pressurized Water Reactors,” EMF-2103(P)(A), Revision 0, April 2003

► SBLOCA

- ◆ RODEX2 - initial fuel gap conductance
- ◆ Portions of RODEX2 integrated into S-RELAP5 code for hot pin response
- ◆ S-RELAP5 – RCS response
- ◆ “PWR Small Break LOCA Evaluation Model, S-RELAP5 Based,” EMF-2328 (P)(A), Revision 0, March 2001

Overview of Fuel Analysis Methodologies

► Neutronics - Core Design and Neutronics Input to Safety

- ◆ EMF-96-029(P)(A), “Reactor Analysis System for PWRs,” Volumes 1 and 2, January 1997. (MICBURN/CASMO-3/PRISM)
 - Benchmarking/validation calculations demonstrate applicability for use on U.S. EPR configurations
 - Adoption of thermal energy cutoff of 0.625 eV
 - Benchmarks to plants with aeroball measurement system
 - Characterizes and evaluates heavy reflector modeling methodology
- ◆ BAW-10221PA, Revision 0, “NEMO-K A Kinetics Solution in NEMO,” October 1998.

► Thermo-Mechanical – Fuel/Fuel Rod Response

- ◆ BAW-10231PA, Revision 1, “COPERNIC Fuel Rod Design Computer Code,” January 2004.

► Thermal Hydraulics – Core Hydraulics and DNB Analysis

- ◆ BAW-10156A, Revision 1, “LYNXT Core Thermal-Hydraulic Program,” August 1993.

Examples of Operating Plants Licensed using AREVA Safety Analysis Methodologies

► Non-LOCA

- ◆ Millstone
- ◆ Robinson
- ◆ Ft. Calhoun
- ◆ St. Lucie
- ◆ Palisades

► SBLOCA

- ◆ Millstone
- ◆ Robinson
- ◆ Ft. Calhoun
- ◆ St. Lucie
- ◆ Harris
- ◆ Palisades

► RLBLOCA

- ◆ Robinson
- ◆ Ft. Calhoun
- ◆ Palisades
- ◆ North Anna
- ◆ Sequoyah

Applicability to U.S. EPR Design

► The following reports demonstrate applicability to the U.S. EPR:

- ◆ Non-LOCA, SBLOCA and Fuels - “Codes and Methods Applicability Report for U.S. EPR,” ANP-10263P-A, Revision 0, AREVA NP Inc., August 2007
- ◆ RLBLOCA - “U.S. EPR Realistic Large Break Loss of Coolant Accident,” ANP-10278P, Revision 0, AREVA NP Inc., March 2007 – In NRC Review
- ◆ SBLOCA - “Small-Break LOCA and Non-LOCA Sensitivity Studies and Methodology,” ANP-10291(P), Revision 0, AREVA NP Inc., October 2007 – In NRC Review
 - SG nodalization sensitivity analyses requested by the NRC during its review of ANP-10263P-A
 - Incorporates modifications of SBLOCA methodology for U.S. EPR and an updated sample problem

► Applicability justified by event

- ◆ Describe transient, when necessary, by phase
- ◆ Identify important components/functionality
- ◆ Identify important phenomena
- ◆ Confirm phenomena same as for currently operating 4-loop PWRs

Summary

- ▶ **AREVA safety analysis methodologies are mature**
 - ◆ Rod ejection was revised to satisfy new SRP 4.2 requirements
 - ◆ Approved for application to numerous operating plants
- ▶ **U.S. EPR design, a 4-loop PWR with RSGs, is similar to current 4-loop designs**
 - ◆ Similar operating conditions
 - ◆ Same phenomena
 - ◆ Within range of applicability of constitutive models
- ▶ **Methodologies are applicable to U.S. EPR design**
 - ◆ Input models adapted to account for unique features
 - ◆ Produce expected results
