ENCLOSURE 1

Clinch River Nuclear Site
Construction Permit Application
Enclosure 3, Preliminary Safety Analysis Report
(Public Version)

Security-Related Information - Withheld Under 10 CFR 2.390

TENNESSEE VALLEY AUTHORITY

Clinch River Nuclear Site Preliminary Safety Analysis Report

Construction Permit Application – Enclosure 2

Revision 0

TABLE OF CONTENTS

CHAPTER 1 INTRODUCTION AND GENERAL PLANT DESCRIPTION 1.1-1

1.1 Introduction 1.1-1

1.2 General Plant Description 1.2-1

1.3 Comparison with Similar Facility Designs 1.3-1

1.4 Identification of Agents and Contractors 1.4-1

1.5 Requirements for Further Technical Information 1.5-1

1.6 Material Referenced 1.6-1

1.7 Drawings and Other Detailed Information 1.7-1

1.8 Incorporation by Reference of the Site Safety Analysis Report 1.8-1

1.9 Regulatory Conformance 1.9-1

1.10 Nuclear Power Plants to Be Operated on Multi-Unit Site 1.10-1

CHAPTER 2 SITE CHARACTERISTICS AND SITE PARAMETERS 2.0-1

2.0 Plant Parameter Envelope Evaluation 2.0-1

2.1 Geography and Demography 2.1-1

2.2 Nearby Industrial, Transportation and Military Facilities 2.2-1

2.3 Meteorology 2.3-1

2.4 Hydrologic Engineering 2.4-1

2.5 Geology, Seismology, and Geotechnical Engineering 2.5-1

CHAPTER 3 DESIGN OF STRUCTURES, SYSTEMS, AND COMPONENTS 3.1-1

3.1 Compliance with U.S. Nuclear Regulatory Commission General Design Criteria 3.1-1

3.2 Classification of Structures, Systems, and Components 3.2-1

3.3 Wind and Tornado Loadings 3.3-1

3.4 Water Level (Flood) Design 3.4-1

3.5 Missile Protection 3.5-1

3.6 Protection Against Dynamic Effects Associated with the Postulated Rupture of Piping 3.6-1

3.7 Seismic Design 3.7-1

3.8 Design of Seismic Category I Structures 3.8-1

3.9 Mechanical Systems and Components 3.9-1

3.10 Seismic and Dynamic Qualification of Mechanical and Electrical Equipment 3.10-1

TABLE OF CONTENTS

3.11 Environmental Qualification of Mechanical and Electrical Equipment 3.11-1

3.12 ASME Code Class 1, 2, and 3 Piping Systems, Piping Components and Their Associated Supports 3.12-1

3.13 Threaded Fasteners – ASME Code Class 1, 2, and 3 . . . . . 3.13-1

APPENDIX 3A PRELIMINARY CLASSIFICATION OF STRUCTURES, SYSTEMS, AND COMPONENTS 3A-1

APPENDIX 3B INTEGRATED REACTOR BUILDING FINITE ELEMENT MODEL 3B-1

APPENDIX 3C SEISMIC SOIL STRUCTURE INTERACTION ANALYSIS RESULTS. 3C-1

APPENDIX 3D INTERACTION EVALUATIONS RESULTS 3D-1

APPENDIX 3E RESPONSES TO STATIC LOADS 3E-1

APPENDIX 3F DESIGN DETAILS AND EVALUATION RESULTS FOR THE CONTAINMENT. 3F-1

APPENDIX 3G DESIGN DETAILS AND EVALUATION RESULTS FOR THE CONTAINMENT INTERNAL STRUCTURES 3G-1

APPENDIX 3H DESIGN DETAILS AND EVALUATION RESULTS FOR THE REACTOR BUILDING STRUCTURE 3H-1

APPENDIX 3I COMPUTER PROGRAMS USED IN THE DESIGN AND ANALYSIS OF SEISMIC CATEGORY STRUCTURES. 3I-1

APPENDIX 3J COMPUTER PROGRAMS USED IN THE DESIGN AND ANALYSIS OF STRUCTURES, SYSTEMS AND COMPONENTS – MECHANICAL DESIGN 3J-1

APPENDIX 3K COMPUTER PROGRAMS USED IN THE DESIGN AND ANALYSIS OF STRUCTURES, SYSTEMS AND COMPONENTS – NUCLEAR FUELS 3K-1

APPENDIX 3L COMPUTER PROGRAMS USED IN THE DESIGN AND ANALYSIS OF STRUCTURES, SYSTEMS AND COMPONENTS – ENVIRONMENTAL AND RADIOLOGICAL 3L-1

APPENDIX 3M COMPUTER PROGRAMS USED IN THE DESIGN AND ANALYSIS OF STRUCTURES, SYSTEMS AND COMPONENTS - SAFETY ANALYSES (PROBABILITY RISK ASSESSMENT AND DETERMINISTIC) 3M-1

APPENDIX 3N AIRCRAFT IMPACT ASSESSMENT 3N-1

CHAPTER 4 REACTOR 4.1-1

4.1 Summary Description 4.1-1

TABLE OF CONTENTS

4.2 Fuel System Design 4.2-1
4.3 Nuclear Design 4.3-1

TS	Technical Specifications
TSC	Technical Support Center
TVA	Tennessee Valley Authority
UHS	Ultimate Heat Sink
USCS	United States Customary System
USNRC	U.S. Nuclear Regulatory Commission

CHAPTER 1 INTRODUCTION AND GENERAL PLANT DESCRIPTION

1.1 Introduction

This Preliminary Safety Analysis Report (PSAR) supports the TVA Construction Permit Application (CPA) for a single unit, Small Modular Reactor (SMR) plant at the Clinch River Nuclear (CRN) Site. The plant is designated as Clinch River Nuclear Unit 1 (CRN-1). The purpose of the PSAR is to describe the proposed facility and the safety analyses that have been performed to evaluate whether the plant can be constructed and operated without undue risk to the health and safety of the public. The PSAR content is consistent with regulatory requirements provided in Title 10 of the Code of Federal Regulations (CFR) Section 50.34.

The CRN Site is located in the City of Oak Ridge, Tennessee, and is the site of the former Clinch River Breeder Reactor Project. The CRN Site is comprised of approximately 935 acres, which are adjacent to the Clinch River arm of the Watts Bar Reservoir. The CRN Site is described in the "Clinch River Nuclear Site Early Site Permit (ESP) Application Part 2, Site Safety Analysis Report," (Reference 1.1-1). Portions of Part 2 of the ESP Application, (i.e., the Site Safety Analysis Report (SSAR)), are incorporated by reference in this PSAR. As summarized in the "Final Safety Evaluation Report for the Early Site Permit Application for the CRN Site," (Reference 1.1-2), SMRs having design characteristics consistent with the ESP Application and meeting the terms and conditions of the Final Safety Evaluation Report (FSAR) can be safely located at the CRN Site.

This PSAR is based on the construction of a BWRX-300 SMR designed by GE Hitachi Nuclear Energy (GEH) with a nominal electrical output of 300 MWe.

The projected completion date is Government Fiscal Year (FY) 2032. Anticipated commercial operation is FY 2033.

1.1.1 Format and Content

Regulatory Guide (RG) 1.70, "Standard Format and Content of Safety Analysis Reports for Nuclear Power Plants (NPPs) Light Water Reactor (LWR) Edition," provides guidance on the format and content of Safety Analysis Reports and is the basis of this PSAR. Because the PSAR supports a CPA, design information is preliminary and is sufficient to assess and demonstrate the safety of the design. The PSAR will be updated after issuance of a Construction Permit (CP) to a FSAR, which provides the design information needed to support an Operating License (OL). In situations where there is uncertainty as to whether material is to be provided in the PSAR or FSAR, a statement is provided to clarify information that will be presented in the FSAR.

Consistent with common licensing practice, most of the PSAR text is written in present tense, active voice, including discussions of facilities and programs not yet built or implemented. Exceptions to this approach include discussion of completed studies and evaluations, which are written in the past tense. It should be understood, however, that statements regarding facilities (e.g., Structures, Systems, and Components (SSCs)) and pre-construction, preoperational, and operational activities (e.g., procedures and programs) typically address activities that have not yet been performed and will not be performed until it is reasonable and appropriate to do so.

1.1.1.1 Standard Review Plan

Nuclear Regulatory Report (NUREG)-0800, “Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants: LWR Edition,” also referred to as the Standard Review Plan (SRP), provides regulatory guidance and acceptance criteria to support a U.S. Nuclear Regulatory Commission (USNRC) safety evaluation. A review of the facility against the SRP revision in effect as of January 1, 2025, was performed. Subsection 1.9.2 summarizes this review with an explanation of conformance with applicable SRP acceptance criteria.

Section numbering in this PSAR generally aligns with the SRP numbering with significant differences as follows:

- Chapter 7, Instrumentation and Controls is presented in terms of the “Design Review Guide (DRG): Instrumentation and Controls for Non-Light-Water Reactor (Non-LWR) Reviews,” (Reference 1.1-3), in lieu of SRP Section 7.
- Chapter 15, Transient and Accident Analysis is presented in terms of International Atomic Energy Agency (IAEA) SSG-61, “Format and Content of the Safety Analysis Report for Nuclear Power Plants,” (Reference 1.1-4), in lieu of SRP Section 15.
- Chapter 18, Human Factors Engineering, as defined by SRP Section 18, will be provided in the FSAR.
- Chapter 19, Severe Accidents, as defined by SRP Section 19, will be provided in the FSAR. Section 15.6 provides risk insights available at the time of the PSAR submittal.

1.1.1.2 Tables, Figures, and Page Numbering

Tables, figures, and page numbering correspond to the PSAR section number at the “X.Y” level followed by a specific numerical identification, (e.g., Table 1.2-3 refers to the 3rd table in Section 1.2).

Summary information is presented in tables. If a table used in the SSAR is revised for use in the PSAR, the original SSAR table number is appended with an “R;” for example, “SSAR Table 2.0-2” is revised and it is labeled in this PSAR as “Table 2.0-2R.” Tables are located at the end of the applicable section.

Figures, graphs, and diagrams are provided with the level of detail needed to support the safety analysis. Thus, the PSAR does not provide detailed engineering drawings or figures drawn to scale. If a figure from the SSAR is reproduced in the PSAR, it is identified accordingly. If a figure from the SSAR is revised for use in the PSAR, the original SSAR figure number is appended with an “R;” for example, “SSAR Figure 1.2-1” is revised and it is labeled in the PSAR as “Figure 1.2-1R.” Figures are located at the end of the applicable section following the tables.

1.1.1.3 Numerical Information

Calculation output and data are provided with the number of significant figures that reflect the accuracy of the calculation and data. Similarly, values of design parameters such as power

output or component dimensions are “nominal” rather than “as-built” values. Units are presented in United States Customary System (USCS), International System of Units (SI), or both.

1.1.1.4 Organization

The PSAR is organized into the following chapters:

Chapter 1: Introduction and General Plant Description

Chapter 1 summarizes the principal aspects of the design, conformance with regulatory requirements and guidance, and material that is incorporated by reference in the PSAR.

Chapter 2: Site Characteristics

Chapter 2 provides site characteristics and siting parameters for the CRN Site.

Chapter 3: Design of Structures, Systems, and Components

Chapter 3 describes the classification of SSCs as well as compliance with General Design Criteria (GDC) and Principal Design Criteria (PDC).

Chapter 4: Reactor

Chapter 4 describes the design of the nuclear fuel, reactor, and reactor core, including the fuel rods, fuel assemblies, reactivity control system, nuclear design, and thermal-hydraulic parameters.

Chapter 5: Reactor Coolant System and Connected Systems

Chapter 5 describes the Reactor Coolant System (RCS) and connected systems that form the Reactor Coolant Pressure Boundary (RCPB).

Chapter 6: Engineered Safety Features

Chapter 6 describes Engineered Safety Features (ESFs) provided to mitigate the consequences of postulated accidents.

Chapter 7: Instrumentation and Controls

Chapter 7 describes Instrumentation and Controls (I&C) systems used for normal, abnormal, and accident conditions.

Chapter 8: Electric Power

Chapter 8 describes the Alternating Current (AC) and Direct Current (DC) power systems and power requirements for normal, abnormal, and accident conditions.

Chapter 9: Auxiliary Systems

Chapter 9 describes systems used to support fuel storage and handling, normal cooling water, process auxiliaries (such as compressed air, sampling, water chemistry, containment inerting), heating, ventilation and cooling, fire protection, power auxiliaries, communications, and lighting.

Chapter 10: Steam and Power Conversion System

Chapter 10 describes the systems used for steam and power conversion with a representative heat balance presented.

Chapter 11: Radioactive Waste Management

Chapter 11 describes the capabilities of the plant to control, collect, handle, process, store, and dispose of liquid, gaseous, and solid wastes that may contain radioactive materials, and the instrumentation used to monitor and control the release of radioactive effluents and wastes.

Chapter 12: Radiation Protection

Chapter 12 describes policy, design and operational considerations that ensure occupational radiation exposure to personnel is kept As Low As Reasonably Achievable (ALARA).

Chapter 13: Conduct of Operations

Chapter 13 describes the CRN-1 organizational structure, programs and procedures developed to support safe plant operation during normal, abnormal, and accident conditions, and provisions for establishing and maintaining a qualified staff. Chapter 13 also describes emergency preparedness, physical security, and fitness for duty.

Chapter 14: Initial Test Program

Chapter 14 describes the initial test program for SSCs and design features to verify the capability to meet functional requirements.

Chapter 15: Safety Analyses

Chapter 15 describes the results of the safety analyses based on a Hazard Analysis, Deterministic Safety Analysis, and Probabilistic Safety Assessment.

Chapter 16: Technical Specifications

Chapter 16 provides the methodology for developing Technical Specifications (TS) and associated bases that ensure compliance with the safety analysis inputs, assumptions, and results.

Chapter 17: Quality Assurance

Chapter 17 describes the Quality Assurance (QA) program used during the design and construction of CRN-1 to ensure conformance with regulatory requirements and the design bases specified in the CPA.

1.1-4 IAEA SSG-61, “Format and Content of the Safety Analysis Report for Nuclear Power Plants,” International Atomic Energy Agency, 2021.

1.2 General Plant Description

A summary description of the CRN Site and CRN-1 follows.

1.2.1 Principal Site Characteristics

The CRN Site is defined in the SSAR and Chapter 2. Portions of the SSAR (Reference 1.1-1) are incorporated by reference in this PSAR as itemized in Section 1.8. The CRN Site location is shown in Figure 1.2-1R.

1.2.2 Plant Description

The CRN-1 plant, a BWRX-300 design, is a water-cooled SMR with core heat removal by natural circulation. The Balance of Plant design is based on standard components in use throughout the BWR fleet adjusted for gross power output. The steam and power conversion system for the BWRX-300 consists of the following systems: Turbine Generator (TG), Main Steam subsystem (MS) of the Nuclear Boiler system (NBS), Main Condenser and Auxiliaries (MCA), Moisture Separator Reheater System (MSR), Turbine Gland Seal System (TGSS), Turbine Bypass System (TBS), Circulating Water System (CWS), Condensate Filters and Demineralizers (CFD), and the Condensate and Feedwater Heating System (CFS).

Fuel storage for new and spent fuel is in the fuel pool located in the Reactor Building (RB). The fuel racks are designed to hold a reload of fresh fuel and at least 5 years of spent fuel with space remaining for a full core of off-loaded fuel.

Systems performing Safety Category 1 functions are simple and driven by natural passive mechanisms based on fundamental physical and thermodynamic principles. In the event of a Design Basis Accident (DBA), reactor shutdown, Reactor Pressure Vessel (RPV) heat removal, RPV isolation, containment heat removal, and containment isolation are achieved without reliance on AC power. Key safety features of the design are summarized, as follows:

- Passive plant: Safety Category 1 functions are not dependent on external sources of power nor operator action to control reactivity, remove heat from the fuel, and confine the radioactive material for 72 hours after a DBA.
- RPV design: The RPV height is increased, relative to a forced circulation BWR, with a tall chimney region. The natural circulation flow resulting from the increased height provides adequate thermal margins during power operations and off-normal conditions. RPV nozzles are located above the Top of Active Fuel (TAF).
- Reactor Isolation Valves (RIV): Integral RIVs are directly flanged to the RPV nozzles on the reactor vessel. The RIVs allow LOCAs to be quickly isolated, thereby preserving the fluid inventory in the RPV for core cooling.
- Isolation condensers: The passive Isolation Condenser System (ICS) provides residual and decay heat removal, overpressure protection, and is the Emergency Core Cooling System (ECCS) in conjunction with the RIVs. The IC pools are the ultimate heat sink for the ICS, thereby cooling the reactor core.

- RCPB Safety and relief valves: Safety and relief valves for the RCPB are not required in the design. The ICS, in conjunction with the reactor scram function, provides overpressure protection for the RCPB.
- Containment design:
  - The containment is comprised of a Steel-Plate Composite (SC) Containment Vessel (SCCV), consisting of cylindrical wall, mat foundation, and top slab; a steel containment closure head, and other ASME Boiler and Pressure Vessel Code (BPVC), Section III, Division 1, Class MC components. The containment is enclosed within an RB that is largely below grade.
  - The containment is nitrogen inerted and has limited subcompartments with large openings. Analyses demonstrate the subcompartments are sufficiently mixed and that gases generated by radiolysis do not create a deflagration concern.
  - The Passive Containment Cooling System (PCCS) is a passive system for transferring heat by natural circulation from the containment atmosphere to the reactor cavity pool and equipment pool to maintain containment pressure and temperature within the design limits during accident conditions, or loss of active containment cooling provided by the Containment Cooling System. The reactor cavity pool and equipment pool can provide containment heat removal for 72 hours without operator action following a DBA.
- Containment Isolation Valves (CIV): The containment isolation function assures containment integrity while allowing the passage of fluids across the boundary as needed to mitigate a postulated accident. To support isolation of fluid lines penetrating containment, CIVs are included in each process system line and instrumentation line. Containment penetrations are designed to maintain structural integrity during environmental conditions resulting from a postulated accident and protect against leakage from the containment.
- Emergency Power Systems: The emergency power systems consist of three independent divisions of DC power. Only two of the three corresponding Emergency Power System divisions are required to mitigate a DBA.

  AC power is not required to support SC1 loads. Emergency Power System batteries provide 72-hours' worth of power to loads supporting Safety Category 1 functions and Post-Accident Monitoring (PAM).

Table 1.2-1 provides key design characteristics of the BWRX-300.

1.2.3 General Arrangements of Major Structures

General arrangement drawings illustrating major structures are provided in Figure 1.2-3 through Figure 1.2-15. Table 1.2-2 provides the size of Power Block buildings.

Table 1.2-1 Key Design Characteristics

Characteristic	Value
Intended purpose	Commercial electric power generation with load following capability
Reference site design	Single unit
Type of plant	Boiling Water Reactor (BWR)
Core coolant, moderator	Light water, light water
Nuclear Steam Supply System layout	Direct-Cycle
Primary circulation	Natural
Gross electrical output (nominal)	300 MWe
Reactor thermal power level (estimated)	870 MWth
Type of containment structure	Dry
Containment construction	Steel-plate composite
Normal Heat Sink	Once through cooling system
Ultimate Heat Sink	IC pools, fuel pool, reactor cavity pool, and equipment pool
Fuel enrichment	3.84 to 4.68 w/o U235
Fuel cladding	Zircaloy-2
Number of fuel bundles	240
RPV diameter (ID)	~ 4 m
RPV height (Inside)	~ 27 m
Spent fuel pool capacity	At least 5 years of full-power operation plus a full core
Emergency Power Supply	SC1 DC batteries
Design life	60 years

Table 1.2-2 Size of Power Block Buildings

	Turbine Building	Radwaste Building	Control Building	Service Building
Length:	65.9m	40.4m	30.6m	30.6m
Width:	66.9m	23.4m	33.8m	28.8m
Height:	36.0m	20m	20m	20m

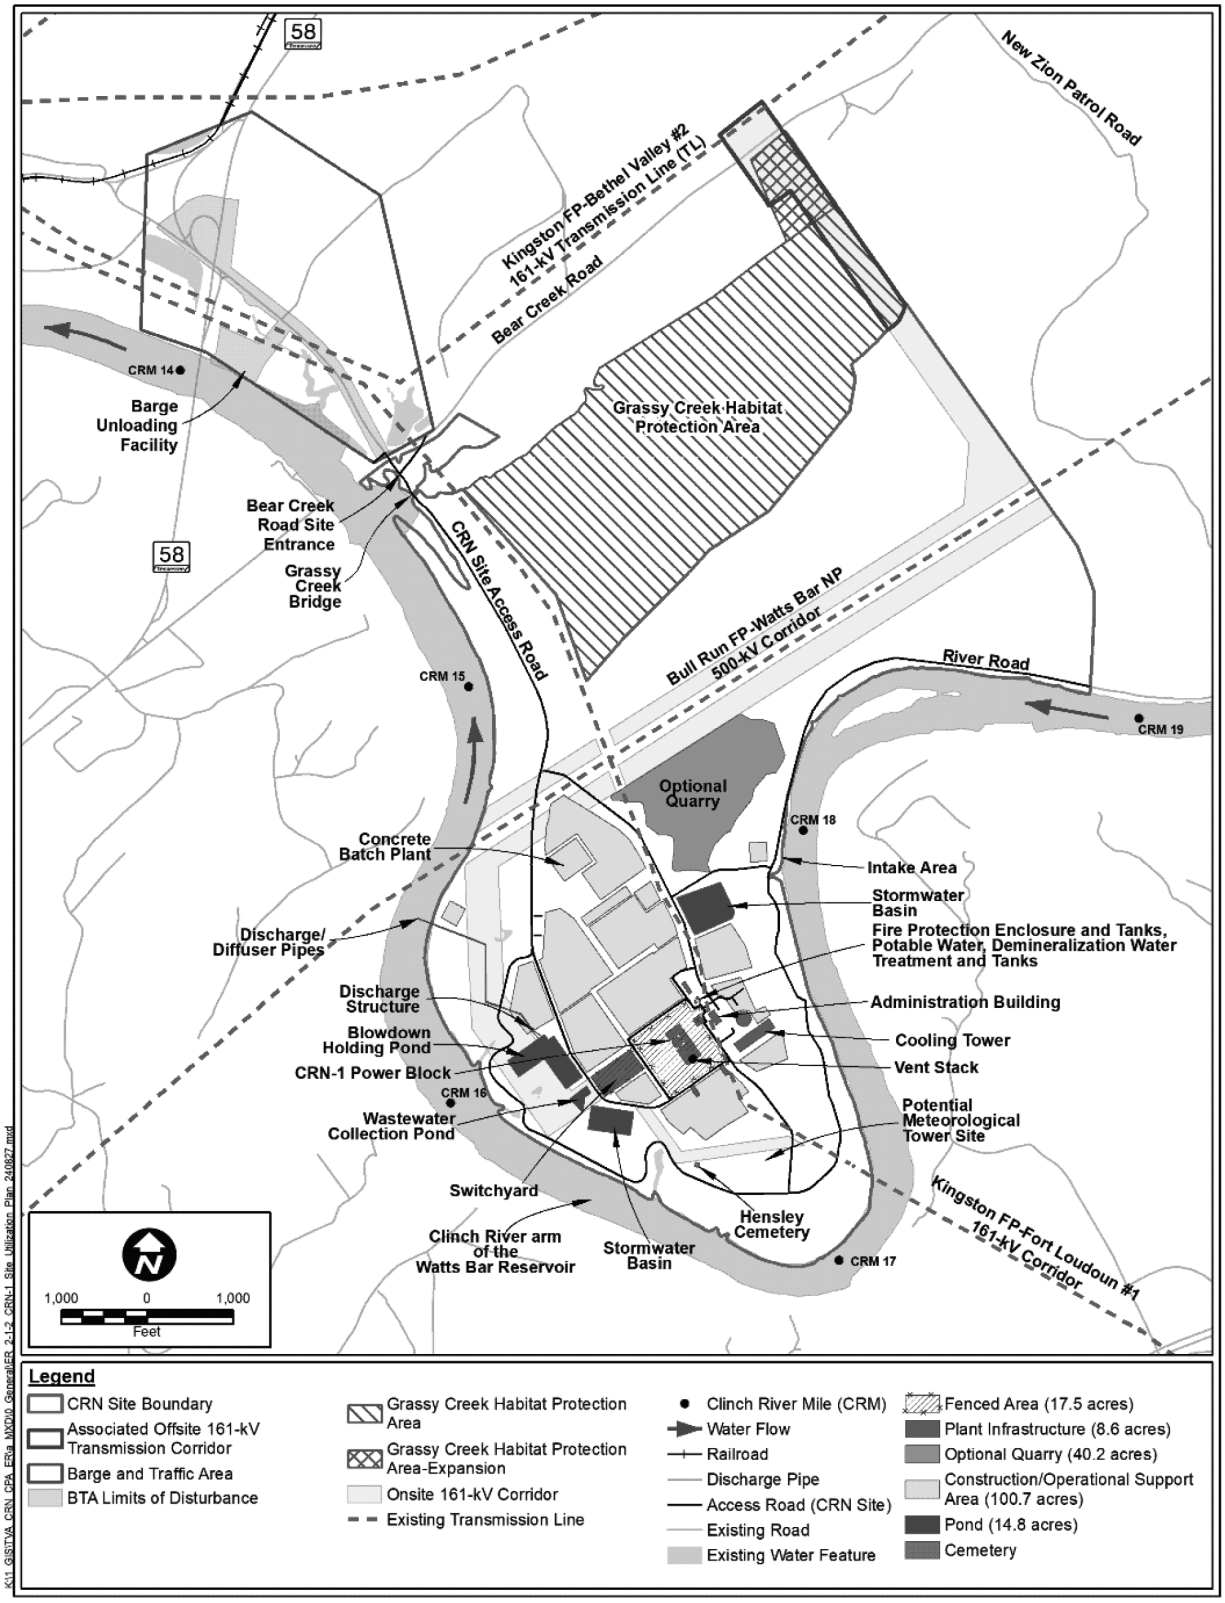
Notes:

1. Values are approximate.
2. Height does not include the exhaust stack or stairs.
3. Equipment structures around Turbine Building, Radwaste Building, and Control Building are not included in the Power Block footprint.

Outer Diameter of Reactor Building	37.0m
Inner Diameter of Reactor Building	35.2m
Outer Diameter of Containment	19.9m
Inner Diameter of Containment	17.5m
Height Above Level 0m	32.7m

Note:

1. Values are approximate.



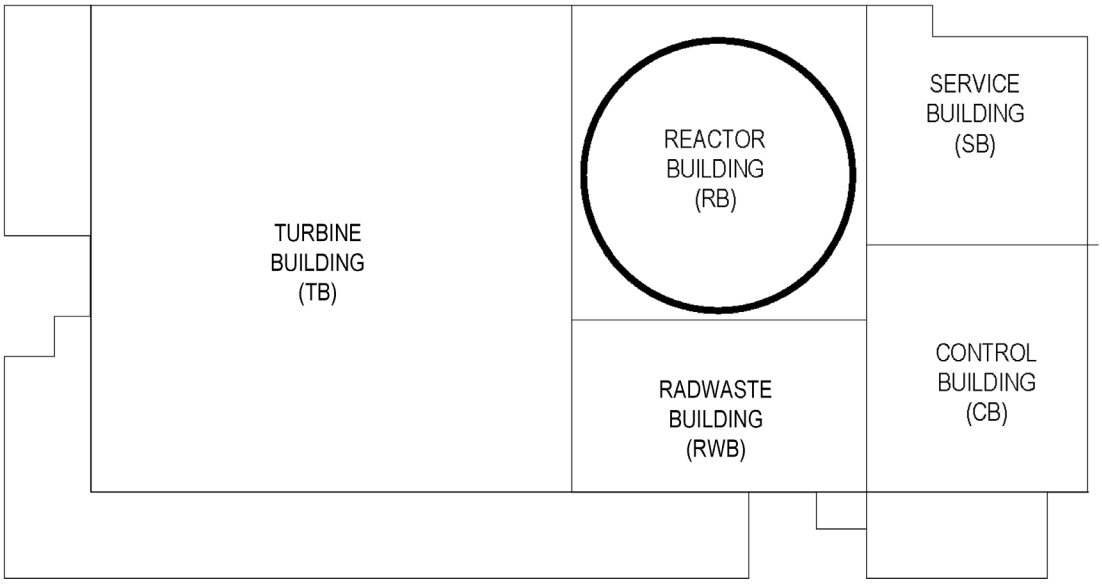


Figure 1.2-1R Clinch River Site

Note:

The Power Block structure consists of the Reactor Building, Turbine Building, Radwaste Building, Control Building, and the Service Building. Equipment structures around the Turbine Building, Radwaste Building, and Control Building are not included in the Power Block footprint.

1.3 Comparison with Similar Facility Designs

The BWRX-300 is the tenth generation of the BWR and is the simplest in the BWR product line. The BWRX-300 is the next evolution of the Economic Simplified Boiling Water Reactor (ESBWR) which received design certification (Appendix E to 10 CFR Part 52) and the Advanced Boiling Water Reactor (ABWR) which received design certification (Appendix A to 10 CFR Part 52).

The BWRX-300 incorporates the lessons learned in design, construction, operations, and maintenance from the many generations of BWRs that have been designed, built, and are currently operating or have been decommissioned. The BWRX-300 is designed to enhance safety through simplification and reducing dependence on human intervention. This is achieved through increasing its reliance on natural circulation and natural phenomena-driven safety systems. These safety enhancements, in combination with its reduction in scale and complexity, enable reductions in operating staff, maintenance, and security requirements, as well as being easier to decommission.

Table 1.3-1 provides a comparison of facilities with similar designs.

Table 1.3-1 Comparison of Facilities with Similar Designs

Feature	ABWR	ESBWR	BWRX-300
Plant Type	Direct Cycle BWR	Direct Cycle BWR	Direct Cycle BWR
Plant Gross Electrical Output	~1,350 MWe	~1,600 MWe	~300 MWe
Reactor Coolant Recirculation	Reactor Internal Pumps	Natural Circulation	Natural Circulation
RPV Diameter (ID)	7.1 m	7.1 m	~4 m
RPV Height (Inside)	21.1 m	27.6 m	~27 m
Fuel Type	GE14	GNF14	GNF2
Number of Fuel Bundles	872	1,132	240
Fuel Rod Cladding Material	Zircaloy-2	Zircaloy-2	Zircaloy-2
Control Rod Blade Type	Cruciform B4C (optional Hf edges/tips)	Cruciform B4C (optional Hf edges/tips)	Cruciform B4C (optional Hf edges/tips)
Control Rod Drive (CRD) Type	Bottom Entry Fine Motion Control Rod Drive (FMCRD)	Bottom Entry FMCRD	Bottom Entry FMCRD
Number of Control Rods	205	269	57
Primary Containment Vessel Type	Reinforced Concrete Containment with steel liner	Reinforced Concrete Containment with steel liner	SCCV
Primary Containment Wetwell	Concrete Cylinder	Concrete Cylinder	None
ECCS	Active: 3-Divisional	Passive	Passive
Automatic Depressurization System (ADS)	Safety Relief Valves (SRVs)	SRVs and Depressurization Valves	RIVs and ICS in conjunction with reactor scram used for overpressure protection
Incore Monitor Calibration	Traversing Incore Probe System	Fixed, Incore Gamma Thermometers (GTs)	Fixed, Incore GTs

1.4 Identification of Agents and Contractors

1.4.1 Applicant/Program Manager

TVA is the holder of an Early Site Permit (ESP) at the CRN Site; the ESP has been approved as indicated in the Final Safety Evaluation Report for the CRN Site (ML19162A157). TVA is the applicant for the construction permit at the CRN Site.

TVA is the United States' largest public power provider. It was established by Congress in 1933 to, among other things, improve navigation on the Tennessee River, reduce the damage from destructive floodwaters within the Tennessee River system and downstream on the lower Ohio and Mississippi Rivers, further the economic development of TVA's service area, and sell the electricity generated at the facilities TVA operates. TVA's service territory includes most of Tennessee and parts of Alabama, Georgia, Kentucky, Mississippi, North Carolina, and Virginia.

1.4.2 Principal Contractors and Participants

Experience and qualifications of these agents and contractors, as well as the division of responsibility between TVA and its agents and contractors is discussed below.

TVA design and construction management teams provide oversight of design and construction activities prior to transitioning from the design/construction phase to the operational phase.

GEH is the reactor technology vendor and is responsible for design control of the power block. GEH provides engineering and technical services to the fleet of operating BWRs for the nuclear island, turbine island, and balance of plant equipment; plant life extension; power uprates; performance services; spare and renewal parts; outages; and inspections. GEH has proven experience, knowledge, and capability to design, manufacture, and furnish technical assistance and hardware for the construction, startup, and servicing of the BWRX-300. GEH will provide technical assistance for construction of CRN-1. Operating experience from design, construction, and operation of earlier GEH BWRs is applied in the design, construction, and operation of the BWRX-300.

The contractor responsible for the construction of the project will be Bechtel North American Power Corporation (Bechtel). Bechtel is responsible for procurement, construction, and support of commissioning activities. Additional design engineering for selected site-specific portions of the plant will be performed by Sargent and Lundy, LLC (S&L). These contractors were selected based on experience and proven technical capability in nuclear construction projects or projects of similar scope and complexity.

1.4.2.1 GE-Hitachi Nuclear Energy Americas, LLC

GEH is a business alliance of GE and Hitachi's respective nuclear businesses, established to serve the global nuclear industry. In addition, GE Nuclear Energy (predecessor to GEH) has designed, developed, constructed, and manufactured hardware for nuclear facilities since the 1950s, with the Dresden Unit 1 station being licensed in 1959 as the first United States commercial nuclear facility and the ABWR receiving the first design certification, followed by

ESBWR design certification. GEH has designed and delivered more than 60 commercial nuclear power plants, both domestic and international. GEH is headquartered in Wilmington, North Carolina.

1.4.2.2 Bechtel North American Power Corporation

Bechtel is one of the foremost architect-engineering firms in the United States, with the design and construction of 150 nuclear power projects in 25 countries to its credit. Bechtel has a history of supporting the nuclear power industry, beginning with the construction in 1950 of the EBR-1 reactor. Since then, Bechtel has engineered and constructed more than 60,000 MWe of nuclear power capacity worldwide. Bechtel is the nation’s largest power contractor and is headquartered in San Francisco, California.

1.4.2.3 Sargent and Lundy, LLC

Since 1891, S&L has been a global leader in engineering and design for the power industry. In North America, S&L is currently providing services to over 90 operating nuclear units. Additionally, S&L has been providing international support for the power industry since 1917 with project experience spanning over 90 countries on five continents. S&L is headquartered in Chicago, Illinois.

1.5 Requirements for Further Technical Information

This section identifies, describes, and discusses those safety features or components for which further technical information is required in support of the issuance of a construction permit, but which have not been supplied with the CPA.

The following criteria were used to identify activities that require further technical information for Safety Category 1 functions:

- Unique design features that support the safety analysis
- Adequate margin of conservatism of unique design features that support the safety analysis
- Confirmation of design features for extremely low probability events (e.g., Design Extension Conditions (DEC))

For each activity, this section:

1. Describes the specific technical information that must be obtained to demonstrate acceptable resolution,
2. Describes how the information will be obtained or cross-reference the PSAR section(s) in which the information will be provided,
3. Provides a schedule of completion as related to the projected CRN-1 startup date, and
4. Describes the design alternatives or operational restrictions available if the results do not demonstrate an acceptable resolution.

Design features that are expected to meet established performance criteria, but are subject to on-going evaluations and development of detail design, are not included in this section provided that:

- Similar design configurations have been previously approved by the USNRC
- Applicable operating experience is judged applicable to CRN-1 conditions
- Existence of accepted and applicable codes and standards

On-going activities, where applicable, are described in related PSAR sections.

1.5.1 Seismic Analyses

A. Description

Sections 3.7 and 3.8 describe the seismic and structural design criteria for the BWRX-300 Seismic Category I structures. Appendices 3B through 3H provide a summary of the preliminary analyses that demonstrate how the design of the Seismic Category I structures and associated

foundation comply with the design criteria. The following Appendices will be provided in a Supplement:

Appendix 3B – Integrated Reactor Building Finite Element Model: Appendix 3B presents an overview of the 3-D FE model used in the structural analyses of the integrated RB and describes the various analysis cases and checks performed to validate the model.

Appendix 3C – Seismic Soil Structure Interaction Analysis Results: Appendix 3C provides key seismic stress demands calculated for key structural members of the integrated RB and assesses the effects of subgrade properties on the seismic response of the soil-structure system by comparing Soil-Structure Interaction (SSI) analysis cases.

Appendix 3D – Interaction Evaluations Results: Appendix 3D provides interaction evaluations results of the Seismic Category II and RW-IIa Power Block structures and foundations with the Seismic Category I structures and foundations under extreme loading.

Appendix 3E – Responses to Static Loads: Appendix 3E presents key design parameters and key results of the 1-g static SSI, static and quasi-static, and thermal load cases considered bounding for the design of the BWRX-300 integrated RB structures to identify critical demands on the structures.

Appendix 3F – Design Details and Evaluation Results for the Containment: Appendix 3F provides bounding estimates of the available margins for the SCCV structure based on results from bounding load combinations selected for the evaluation of the containment and discusses the design of critical SCCV Diaphragm Plate Steel-Plate Composite (DP-SC) connections.

Appendix 3G – Design Details and Evaluation Results for the Containment Internal Structures: Appendix 3G provides bounding estimates of the available margins for the RPV Pedestal structure based on results from bounding load combinations selected for the evaluation of the RB structure.

Appendix 3H – Design Details and Evaluation Results for the Reactor Building Structure: Appendix 3H provides bounding estimates of the available margins for key structural members of the RB based on results from bounding load combinations selected for the evaluation of the RB structure and discusses the design of critical RB DP-SC connections.

B. Schedule

Expected Availability: A Supplement will be provided with the Appendices 3B through 3H in the 4th quarter of FY 2025.

C. Alternatives

If the preliminary analyses provided in these appendices do not result in the expected margins to the required acceptance criteria, the structural design features will evolve, as required, to ensure all structural and seismic design criteria are satisfied. Any updates will be communicated to the NRC and provided via a planned update during the CPA review period.

1.5.2 10 CFR 50.34(a)(1)(ii)(D) Evaluation

A. Description

An evaluation assuming a fission product release based on a hypothetical event sequence resulting in core melt will be performed in accordance with 10 CFR 50.34(a)(1)(ii)(D). The hypothetical event sequence and associated fission product release is design-specific and will be analyzed using Modular Accident Analysis Program (MAAP) or suitable alternative as a Design Extension Condition. The ARCON computer program will be used to evaluate the short-term offsite and on-site atmospheric dispersion factors (χ/Qs). The dose consequences will be calculated using RADTRAD and evaluated against dose criteria specified in 10 CFR 50.34(a)(1)(ii)(D) and PDC 19, Control Room.

B. Schedule

Expected Availability: Supplement will be provided with the described evaluation within six months of the CPA submittal.

C. Alternatives

Additional iteration between design and analysis may be necessary to achieve compliance with acceptance criteria. Any updates will be communicated to the NRC and provided via a planned update during the CPA review period.

1.6 Material Referenced

Documents that are incorporated by reference into the PSAR are identified using the bases provided in Nuclear Energy Institute (NEI) 98-03, “Guidelines for Updating Final Safety Analysis Reports,” (Reference 1.6-1), which is endorsed by RG 1.181. Subsection 1.6.1 lists Topical Reports which provide BWRX-300 design information that supports the CPA.

Incorporation of the SSAR is addressed in Section 1.8.

1.6.1 Topical Reports

The following Topical Reports are Incorporated By Reference:

- NEDC-33922P-A, “BWRX-300 Containment Evaluation Method,” (Reference 1.6-2), discusses the analysis method used for the thermal hydraulics performance to demonstrate that the containment design satisfies the acceptance criteria listed in NEDC-33911P-A, “BWRX-300 Containment Performance,” (Reference 1.6-4).
- NNP-TR-001-NP-A, “Quality Assurance Program Description for TVA New Nuclear,” (Reference 1.6-3), describes the quality program for the site-selection, design, construction, and operation of CRN-1.

Other topical or technical reports referenced in the PSAR provide design and analysis information that supports the CPA.

1.9 Regulatory Conformance

This section addresses compliance with regulatory requirements and conformance with regulatory guidance.

1.9.1 Compliance with General Design Criteria

Section 3.1 provides a summary of compliance to 10 CFR 50 Appendix A, General Design Criteria.

1.9.2 Conformance with Standard Review Plan

With the exception of Table 1.9-7, Table 1.9-1 through Table 1.9-19 summarize conformance with SRP Acceptance Criteria provided in NUREG-0800. The tables list each SRP, revision, title, SRP Acceptance Criteria, topic, conformance, and PSAR section. SRP Acceptance Criteria are based on latest revision at the time of this submittal; draft revisions are not addressed. The PSAR Section column identifies where each criterion is addressed, if applicable. If the criterion is not applicable, the PSAR Section column includes N/A with an explanation provided in the Conformance column. The Conformance column summarizes alternatives to an SRP Acceptance Criteria. Branch Technical Positions (BTP) are included in the table and dispositioned in the manner of SRP Acceptance Criteria.

The “Design Review Guide (DRG): Instrumentation and Controls for Non-Light-Water Reactor (Non-LWR) Reviews,” (Reference 1.9-1), is used in lieu of SRP Chapter 7. The DRG provides guidance for the USNRC to use in reviewing the I&C portions of applications for advanced non-LWRs within the bounds of existing regulations. Table 7.3-5, Table 7.3-6, Table 7.3-7, and Table 7.3-8 depict how the BWRX-300 design meets the DRG based on the equipment safety classification.

1.9.3 Conformance with Regulatory Guides

Table 1.9-20 summarizes conformance with RGs. The table lists each RG, revision, title, conformance, alternatives, and PSAR section. The table is based on the RG revision as of January 2025. The table does not include RG drafts, those released for trial use, or those that have been withdrawn. The PSAR Section column identifies where the RG is addressed, if applicable. If the RG is not applicable, the PSAR Section column includes N/A with an explanation provided in the Alternatives column. The Alternatives column also identifies partial conformance with an explanation; a blank indicates that there are no alternatives.

The conformance evaluation was performed on the following Regulatory Guide Divisions:

- Power Reactors (Division 1)
- Environmental and Siting (Division 4)
- Materials and Plant Protection (Division 5)
- Occupational Health (Division 8)

The following Regulatory Guide Divisions do not apply to the SAR of a power reactor and are not included in Table 1.9-20:

- Research and Test Reactors (Division 2)
- Fuels and Materials Facilities (Division 3)
- Products (Division 6)
- Transportation (Division 7)
- Antitrust and Financial Review (Division 9)
- General (Division 10)

1.9.4 Compliance with Three Mile Island Requirements

10 CFR 50.34(f) describes Three Mile Island (TMI) additional requirements for light water reactor construction permit applicants. The TMI requirements specify information to demonstrate that 10 CFR 50.34(f)(1) and 10 CFR 50.34(f)(2) required actions are satisfactorily completed, should be available as part of the FSAR, or by the operating license stage, respectively. In certain cases, TVA has elected to provide TMI compliance information in the PSAR to support related information in other PSAR chapters.

In addition, 10 CFR 50.34(f) requirements specify that applicants for design certifications and combined licenses shall demonstrate compliance with the technically relevant portions of the requirements in paragraphs (f)(1) through (f)(3), except for paragraphs (f)(1)(xii), (f)(2)(ix), and (f)(3)(v). Section 4.1.1 of NEDC-33910P-A, “BWRX-300 Reactor Pressure Vessel Isolation and Overpressure Protection,” (Reference 1.9-2), identifies and provides a basis for the TMI containment requirements that are not technically relevant. The USNRC acknowledged in the Safety Evaluation that certain TMI requirements were not technically relevant subject to confirmation for a final design. An exemption is not considered necessary because 10 CFR 50.34(f) was intended for traditional LWRs, in lieu of LWRs and non-LWRs with simplified designs and passive safety systems.

TMI requirements that are not technically relevant to the BWRX-300 design are identified in Table 1.9-21.

Table 1.9-21 presents compliance with TMI Requirements as prescribed by 10 CFR 50.34(f). The table provides the regulation subsection, description of the requirement, compliance status, comments, and PSAR section. The PSAR Section column identifies where the regulation is addressed, if applicable. If the regulation is not applicable, the PSAR Section column includes N/A with an explanation provided in the Comments column. The Comments column also identifies partial compliance with an explanation. No entry in the Comments column indicates that the design complies to the TMI Requirement without exception.

1.9.5 Conformance with Advanced and Evolutionary Light Water Reactor Design Issues

Conformance with applicable Commission papers (SECY) and Staff Requirements Memoranda relating to advanced and evolutionary light water reactor design issues are addressed in the relevant sections.

3.11	3	Environmental Qualification of Mechanical and Electrical Equipment	1	Conformance with RG 1.89	Conforms	Table 1.9-20
3.11	3	Environmental Qualification of Mechanical and Electrical Equipment	2	Conformance with IEEE Std 323	Alternate Approach	3.11
3.11	3	Environmental Qualification of Mechanical and Electrical Equipment	3	Conformance with RG 1.40	Conforms	Table 1.9-20
3.11	3	Environmental Qualification of Mechanical and Electrical Equipment	4	Conformance with RG 1.63	Alternate Approach	Table 1.9-20
3.11	3	Environmental Qualification of Mechanical and Electrical Equipment	5	Conformance with RG 1.73	Conforms	Table 1.9-20
3.11	3	Environmental Qualification of Mechanical and Electrical Equipment	6	Conformance with RG 1.89	Conforms	Table 1.9-20
3.11	3	Environmental Qualification of Mechanical and Electrical Equipment	7	Conformance with RG 1.97	Alternate Approach	Table 1.9-20
3.11	3	Environmental Qualification of Mechanical and Electrical Equipment	8	Qualification of cables and field splices; conformance with RG 1.89	Conforms	Table 1.9-20
3.11	3	Environmental Qualification of Mechanical and Electrical Equipment	9	Conformance with RG 1.156	Conforms	Table 1.9-20

Table 1.9-3 Conformance with NUREG-0800 (Chapter 3 Design of Structures, Components, Equipment, and Systems) (Sheet 19 of 21)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
3.11	3	Environmental Qualification of Mechanical and Electrical Equipment	10	Conformance with RG 1.158; RG 1.89	Alternate Approach	Table 1.9-20
3.11	3	Environmental Qualification of Mechanical and Electrical Equipment	11	Conformance with RG 1.180, RG 1.89	Alternate Approach	Table 1.9-20
3.11	3	Environmental Qualification of Mechanical and Electrical Equipment	12	Conformance with RG 1.183	Alternate Approach	Table 1.9-20
3.11	3	Environmental Qualification of Mechanical and Electrical Equipment	13	Effects of chemical exposure	Conforms	3.11.1
3.11	3	Environmental Qualification of Mechanical and Electrical Equipment	14	Process and records for materials, parts, and equipment suitability	Conforms	3.11.2
3.11	3	Environmental Qualification of Mechanical and Electrical Equipment	15	Equipment in a mild environment	Conforms	3.11.1
3.11	3	Environmental Qualification of Mechanical and Electrical Equipment	16	Description of the Environmental Qualification program and milestones	FSAR	FSAR
3.12	1	ASME Code Class 1, 2, and 3 Piping Systems, Piping Components, and Their Associated Supports	A	Analysis methods	Conforms	3.12.1

Table 1.9-3 Conformance with NUREG-0800 (Chapter 3 Design of Structures, Components, Equipment, and Systems) (Sheet 20 of 21)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
3.12	1	ASME Code Class 1, 2, and 3 Piping Systems, Piping Components, and Their Associated Supports	B	Modeling techniques	Conforms	3.12.2
3.12	1	ASME Code Class 1, 2, and 3 Piping Systems, Piping Components, and Their Associated Supports	C	Stress analysis criteria	Conforms	3.12.3
3.12	1	ASME Code Class 1, 2, and 3 Piping Systems, Piping Components, and Their Associated Supports	D	Design of supports	Conforms	3.12.4
3.13	0	Threaded Fasteners – ASME Code Class 1, 2, and 3	1	Design aspects	Conforms	3.13.1
3.13	0	Threaded Fasteners – ASME Code Class 1, 2, and 3	2	Preservice and ISI requirements	Conforms	3.13.2
BTP 3-1	2	Classification of Main Steam Components Other than the Reactor Coolant Pressure Boundary for BWR Plant		Conformance with Table A-1 of BTP 3-1	N/A – BWRX-300 design does not include a main steam isolation valve leakage control system.	N/A
BTP 3-2	2	Classification of BWR/6 Main Steam and Feedwater Components Other than the Reactor Coolant Pressure Boundary	N/A	Main steam and feedwater system components of BWR/6 plants	N/A – applies to BWR/6	N/A

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
4.2	3	Fuel System Design	1.A	Design Basis: Fuel system damage	Conforms	4.2
4.2	3	Fuel System Design	1.B	Design Basis: Fuel rod failure	Conforms	4.2.1
4.2	3	Fuel System Design	1.C	Design Basis: Fuel coolability	Conforms	4.2.4
4.2	3	Fuel System Design	2	Description and design drawings	Conforms	4.2.1
4.2	3	Fuel System Design	3.A	Design evaluation: OPEX	Conforms	4.2.1
4.2	3	Fuel System Design	3.B	Design evaluation: prototype testing	N/A – GNF2 is currently licensed.	N/A
4.2	3	Fuel System Design	3.C	Design evaluation: analytical predictions	Conforms	4.2.1
4.2	3	Fuel System Design	4.A	Testing, inspection, and surveillance plans / testing and inspection of new fuel.	Conforms	4.2.5
4.2	3	Fuel System Design	4.B	Testing, inspection, and surveillance plans / online fuel system monitoring	Conforms	4.2.5
4.2	3	Fuel System Design	4.C	Testing, inspection, and surveillance plans/post-irradiation surveillance	Conforms	4.2.5
4.3	3	Nuclear Design	1	Design limits for power densities and power distributions	Conforms	4.3.4
4.3	3	Nuclear Design	2	Reactivity coefficients	Conforms	4.3.4
4.3	3	Nuclear Design	3.A	Control rod worth and reactivity insertion rate	Conforms	4.3.1
4.3	3	Nuclear Design	3.B	Equipment, operating limits, and procedures	Conforms	4.3.4

Table 1.9-4 Conformance with NUREG-0800 (Chapter 4 Reactor)
(Sheet 2 of 4)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
4.3	3	Nuclear Design	4	Analytical methods and data	Conforms	4.3.3
4.4	2	Thermal and Hydraulic Design	1	Uncertainties	Conforms	4.4.1
4.4	2	Thermal and Hydraulic Design	2	Departure from Nucleate Boiling Ratio, Critical Power Ratio (CPR) limits; Critical Heat Flux (CHF) correlation	Conforms	4.4.1
4.4	2	Thermal and Hydraulic Design	3	Core oscillations and thermal-hydraulic instabilities as described in SRP Section 15.9	Conforms	4.3.6 4A.6 4A.7
4.4	2	Thermal and Hydraulic Design	4	Methods for calculating single-phase and two-phase fluid flow in the reactor vessel and other components	Conforms	4.4.2
4.4	2	Thermal and Hydraulic Design	5	TS, including safety limits and limiting safety settings	Conforms	4.4.2 4.4.4
4.4	2	Thermal and Hydraulic Design	6	Preoperational and initial startup test programs	Conforms	4.6.5
4.4	2	Thermal and Hydraulic Design	7	Loose parts monitoring system	N/A – BWRX-300 does not include a loose parts monitoring system.	N/A
4.4	2	Thermal and Hydraulic Design	8	Accounting for crud in the CHF calculations, pressure drop throughout the RCS; process monitoring	Conforms	4.4.2
4.4	2	Thermal and Hydraulic Design	9	Instrumentation for indications of inadequate core cooling.	FSAR	FSAR

Table 1.9-4 Conformance with NUREG-0800 (Chapter 4 Reactor)
(Sheet 3 of 4)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
4.4	2	Thermal and Hydraulic Design	10	Analyses of Anticipated Transient Without Scram (ATWS) event on fuel design limits consistent with SRP Sections 15.8 and 15.9	Conforms	4.2.4 4A.6 4A.7
4.5.1	3	CRD Structural Materials	1	Materials specifications	Conforms	4.5.1
4.5.1	3	CRD Structural Materials	2	Austenitic stainless-steel components	Conforms	4.5.1
4.5.1	3	CRD Structural Materials	3	Other materials	Conforms	4.5.1
4.5.1	3	CRD Structural Materials	4	Cleaning and cleanliness control	Conforms	4.5.1
4.5.2	3	Reactor Internal and Core Support Structure Materials	1	Materials	Conforms	4.5.3
4.5.2	3	Reactor Internal and Core Support Structure Materials	2	Controls on welding	Conforms	4.5.3
4.5.2	3	Reactor Internal and Core Support Structure Materials	3	Nondestructive examinations	Conforms	4.5.3
4.5.2	3	Reactor Internal and Core Support Structure Materials	4	Austenitic stainless steel	Conforms	4.5.3
4.5.2	3	Reactor Internal and Core Support Structure Materials	5	Other materials	Conforms	4.5.3
4.6	2	Functional Design of Control Rod Drive System	1	CRD System functionality compliance with GDC 4	Conforms	4.6.4
4.6	2	Functional Design of Control Rod Drive System	2	Effect of CRD System failure compliance with GDC 23	Conforms	4.6.4
4.6	2	Functional Design of Control Rod Drive System	3	Single CRD System DS malfunction compliance with GDC 25	Conforms	4.6.4

Table 1.9-4 Conformance with NUREG-0800 (Chapter 4 Reactor)
(Sheet 4 of 4)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
4.6	2	Functional Design of Control Rod Drive System	4	CRD System control and reliability compliance with GDC 26	Conforms	4.6.4
4.6	2	Functional Design of Control Rod Drive System	5	Combined CRD System and ECCS capability compliance with GDC 27	Conforms	4.6.4
4.6	2	Functional Design of Control Rod Drive System	6	CRD System design should preclude RPV components or fuel damage per GDC 28	Conforms	4.6.4
4.6	2	Functional Design of Control Rod Drive System	7	Probability of CRD System function during AOOs per GDC 29	Conforms	4.6.4
4.6	2	Functional Design of Control Rod Drive System	8	Alternate rod injection system and redundant scram header exhaust valves per 10 CFR 50.62I(3)	Conforms	4.6.3
BTP 4-1	3	Westinghouse Constant Axial Offset Control	B	Operating scheme for Westinghouse designs	N/A – applies to Westinghouse designs.	N/A

**Table 1.9-5 Conformance with NUREG-0800 (Chapter 5 Reactor Coolant System and Connected Systems)
(Sheet 1 of 10)**

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
5.2.1.1	4	Compliance with the Codes and Standards Rule, 10 CFR 50.55a	1	Quality standards for compliance with GDC 1	Conforms	5.2.1
5.2.1.1	4	Compliance with the Codes and Standards Rule, 10 CFR 50.55a	2	Design, fabrication, testing of RCPB components in accordance with 10 CFR 50.55a	Conforms	5.2.1
5.2.1.1	4	Compliance with the Codes and Standards Rule, 10 CFR 50.55a	3	Necessary and sufficient ITAAC in accordance with 10 CFR 52.47	N/A – 10 CFR Part 50 CPA	N/A
5.2.1.1	4	Compliance with the Codes and Standards Rule, 10 CFR 50.55a	4	Per 10 CFR 52.79, programs to ensure systems and components meet ASME requirements in accordance with 10 CFR 50.55a.	N/A – 10 CFR Part 50 CPA	N/A
5.2.1.2	4	Applicable Code Cases	1	Quality standards for compliance with GDC 1	Conforms	5.2.1
5.2.1.2	4	Applicable Code Cases	2	Design, fabrication, testing of RCPB components in accordance with 10 CFR 50.55a	Conforms	5.2.1
5.2.1.2	4	Applicable Code Cases	3	Necessary and sufficient ITAAC in accordance with 10 CFR 52.47	N/A – 10 CFR Part 50 CPA	N/A
5.2.1.2	4	Applicable Code Cases	4	Per 10 CFR 52.79, programs to ensure systems and components meet ASME requirements in accordance with 10 CFR 50.55a	N/A – 10 CFR Part 50 CPA	N/A
5.2.2	3	Overpressure Protection	1	Material specifications	Conforms	5.2.3

**Table 1.9-5 Conformance with NUREG-0800 (Chapter 5 Reactor Coolant System and Connected Systems)
(Sheet 2 of 10)**

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
5.2.2	3	Overpressure Protection	2	Design requirements for BWRs operating at power	Conforms	6.3
5.2.2	3	Overpressure Protection	3	Design requirements for Pressurized Water Reactors (PWRs) operating at power	N/A – BWR design	N/A
5.2.2	3	Overpressure Protection	4	Design requirements for PWRs operating at low power (startup, shutdown)	N/A – BWR design	N/A
5.2.2	3	Overpressure Protection	5	Testing and inspections	Conforms	6.3
5.2.2	3	Overpressure Protection	6	Technical Specifications	FSAR	FSAR
5.2.2	3	Overpressure Protection	7	TMI action plan requirements (relief valves and safety valves).	N/A – BWRX-300 design does not include relief and safety valves in the ICS.	N/A
5.2.3	3	Reactor Coolant Pressure Boundary Materials	1	Material specifications	Conforms	5.2.3
5.2.3	3	Reactor Coolant Pressure Boundary Materials	2	Compatibility of materials with reactor coolant	Conforms	5.2.3
5.2.3	3	Reactor Coolant Pressure Boundary Materials	3	Fabrication and processing of ferritic materials	Conforms	5.2.3
5.2.3	3	Reactor Coolant Pressure Boundary Materials	4	Fabrication and processing of austenitic stainless steel	Conforms	5.2.3
5.2.4	2	Reactor Coolant Pressure Boundary Inservice Inspection and Testing	1	System boundary subject to inspection	Conforms	5.2.4
5.2.4	2	Reactor Coolant Pressure Boundary Inservice Inspection and Testing	2	Accessibility	FSAR	FSAR

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
6.1.1	2	Engineered Safety Features Materials	1	Materials and fabrication	Conforms	5.2 6.1
6.1.1	2	Engineered Safety Features Materials	2	Composition and compatibility of ESF fluids	Conforms	6.1
6.1.1	2	Engineered Safety Features Materials	3	Components and systems cleaning	N/A – RG 1.37 has been withdrawn.	N/A
6.1.1	2	Engineered Safety Features Materials	4	Thermal insulation	Conforms	5.2 6.1
6.1.2	3	Protective Coating Systems (Paints)-Organic Materials	1	Coating system inside containment	Conforms	3.8 6.1
6.2.1	3	Containment Functional Design	N/A	Containment Functional Design	N/A – SRP cites other SRP sections for acceptance criteria.	N/A
6.2.1.1.A	3	PWR Dry Containments, Including Subatmospheric Containments	1	Compliance with GDC 16 and GDC 50 regarding design pressure and margin	Conforms	6.2.1
6.2.1.1.A	3	PWR Dry Containments, Including Subatmospheric Containments	2	Compliance with GDC 38 regarding rapid reduction of containment pressure	Conforms	6.2.1
6.2.1.1.A	3	PWR Dry Containments, Including Subatmospheric Containments	3	Compliance with GDC 38 regarding rapid reduction of containment pressure (Subatmospheric containments)	Conforms	6.2.1

Table 1.9-6 Conformance with NUREG-0800 (Chapter 6 Engineered Safety Features)
(Sheet 2 of 13)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
6.2.1.1.A	3	PWR Dry Containments, Including Subatmospheric Containments	4	Compliance with GDC 38 and GDC 50 regarding containment heat removal and design margin (LOCA analysis)	Conforms	6.2.1
6.2.1.1.A	3	PWR Dry Containments, Including Subatmospheric Containments	5	Compliance with GDC 38 and GDC 50 regarding containment heat removal and design margin (secondary system pipe ruptures)	Conforms	6.2.2
6.2.1.1.A	3	PWR Dry Containments, Including Subatmospheric Containments	6	Compliance with GDC 38 and GDC 50 regarding containment heat removal and design margin (external pressure)	Conforms	6.2.1
6.2.1.1.A	3	PWR Dry Containments, Including Subatmospheric Containments	7	Compliance with GDC 13, GDC 64, and 10 CFR 50.34(f)(2)(xvii) regarding post-accident monitoring	Conforms	6.2.1 Table 1.9-21
6.2.1.1.A	3	PWR Dry Containments, Including Subatmospheric Containments	8	Compliance with 10 CFR 50.46 Appendix K.I.D.2 regarding containment pressure for ECCS capability during reflood and spray cooling	N/A – This topic not applicable to the BWRX-300 design.	N/A
6.2.1.1.A	3	PWR Dry Containments, Including Subatmospheric Containments	9	Compliance with GDC 4 regarding internal structures and component capability to withstand differential pressure loadings	Conforms	6.2.1

Table 1.9-6 Conformance with NUREG-0800 (Chapter 6 Engineered Safety Features)
(Sheet 3 of 13)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
6.2.1.1.A	3	PWR Dry Containments, Including Subatmospheric Containments	10	Compliance with 10 CFR 50.34(f)(3)(v)(A)(1) regarding 100% fuel clad metal-water reaction	FSAR	FSAR
6.2.1.1.B	2	Ice Condenser Containments	N/A	Ice Condenser Containments	N/A – BWRX-300 design does not include an ice condenser containment.	N/A
6.2.1.1.C	7	Pressure-Suppression Type BWR Containments	N/A	Pressure-Suppression Type BWR Containments	N/A – BWRX-300 design does not include a pressure-suppression type containment.	N/A
6.2.1.2	3	Subcompartment Analysis	1	Nodalization	Conforms	6.2.1.2
6.2.1.2	3	Subcompartment Analysis	2	Initial thermodynamic conditions	Conforms	6.2.1.2
6.2.1.2	3	Subcompartment Analysis	3	Vent flow path: distribution of released mass and energy	Conforms	6.2.1.2
6.2.1.2	3	Subcompartment Analysis	4	Design pressure	Conforms	6.2.1.2
6.2.1.3	3	Mass and Energy Release Analysis for Postulated LOCAs	1	General Design Criterion 50	Conforms	6.3.3.1 15.5
6.2.1.3	3	Mass and Energy Release Analysis for Postulated LOCAs	1	Appendix K to 10 CFR Part 50	Alternate Approach	6.3.3.1 15.5
6.2.1.3	3	Mass and Energy Release Analysis for Postulated LOCAs	2	10 CFR 52.47(b)(1) regarding ITAAC	N/A – 10 CFR Part 50 CPA	N/A
6.2.1.3	3	Mass and Energy Release Analysis for Postulated LOCAs	3	10 CFR 52.80(a) regarding ITAAC	N/A – 10 CFR Part 50 CPA	N/A

Table 1.9-6 Conformance with NUREG-0800 (Chapter 6 Engineered Safety Features)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
6.2.1.4	2	Mass and Energy Release Analysis for Postulated Secondary System Pipe Ruptures	1	Source of energy	N/A – BWR design	N/A
6.2.1.4	2	Mass and Energy Release Analysis for Postulated Secondary System Pipe Ruptures	2	Mass and energy release rate	N/A – BWR design	N/A
6.2.1.4	2	Mass and Energy Release Analysis for Postulated Secondary System Pipe Ruptures	3	Single failure analysis	N/A – BWR design	N/A
6.2.1.5	3	Minimum Containment Pressure Analysis for Emergency Core Cooling System Performance Capability Studies	1	Containment pressure models meeting 10 CFR 50.46(a)(1(i)	N/A – BWR design	N/A
6.2.1.5	3	Minimum Containment Pressure Analysis for Emergency Core Cooling System Performance Capability Studies	2	Conservatisms in LOCA analyses to meet 10 CFR 50.46(a)(1)(ii)	N/A – BWR design	N/A
6.2.2	5	Containment Heat Removal Systems	1	Containment heat removal system redundancy and power source consistent with ESF design	Conforms	6.2.2
6.2.2	5	Containment Heat Removal Systems	2	Capability of containment spray system to perform safety function	N/A – BWRX-300 design does not include a containment spray system.	N/A

Table 1.9-6 Conformance with NUREG-0800 (Chapter 6 Engineered Safety Features)
(Sheet 5 of 13)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
6.2.2	5	Containment Heat Removal Systems	3	Analysis of containment spray system to perform safety function	N/A – BWRX-300 design does not include a containment spray system.	N/A
6.2.2	5	Containment Heat Removal Systems	4	Containment fan cooler performance capability	N/A – BWRX-300 design does not include containment fan coolers as an ESF system.	N/A
6.2.2	5	Containment Heat Removal Systems	5	Containment heat removal capability per GDC 38	Conforms	6.2.2 9.4.7
6.2.2	5	Containment Heat Removal Systems	6	Containment heat removal capability (long term water source)	N/A – BWRX-300 design does not include a containment spray system and does not require an external water source for ECCS function.	N/A
6.2.2	5	Containment Heat Removal Systems	7	Inspection and testing of containment heat removal system	Conforms	6.2.2
6.2.2	5	Containment Heat Removal Systems	8	Instrumentation for monitoring containment heat removal system performance	Conforms	6.2.2
6.2.3	3	Secondary Containment Functional Design	N/A	Functional capability of secondary containment	N/A – BWRX-300 design does not include a secondary containment	N/A
6.2.4	3	Containment Isolation System	1	Isolation criteria for instrument lines	Conforms	6.2.4

Table 1.9-6 Conformance with NUREG-0800 (Chapter 6 Engineered Safety Features)
(Sheet 6 of 13)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
6.2.4	3	Containment Isolation System	2	Isolation and detection of leakage outside of containment from ESF systems and related systems	Conforms	6.2.1 6.2.2 6.2.4 6.3.5 9.1.3 9.2.8
6.2.4	3	Containment Isolation System	3	Leakage detection of remote-manual isolation valves in systems needed for safe shutdown	Conforms	6.2.4
6.2.4	3	Containment Isolation System	4	Containment isolation valve configuration ESF, safe shutdown lines	Conforms	6.2.4
6.2.4	3	Containment Isolation System	5	Containment isolation valve configuration and protection for ESF systems	Conforms	6.2.4
6.2.4	3	Containment Isolation System	6	Sealed-closed barriers	Conforms	6.2.4
6.2.4	3	Containment Isolation System	7	Relief valves	N/A – BWRX-300 design does not include relief valves as isolation valves.	N/A
6.2.4	3	Containment Isolation System	8	System classification per 10 CFR 50.34(f)(2)(xiv)	Conforms	Table 1.9-21
6.2.4	3	Containment Isolation System	9	Isolation valves outside containment	Conforms	6.2.4

Table 1.9-6 Conformance with NUREG-0800 (Chapter 6 Engineered Safety Features)
(Sheet 7 of 13)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
6.2.4	3	Containment Isolation System	10	Automatic isolation valve position on loss of actuating power	Conforms	6.2.4
6.2.4	3	Containment Isolation System	11	Containment isolation pressure setpoint	Conforms	7.1.3
6.2.4	3	Containment Isolation System	12	Diversity of containment isolation parameters	Conforms	7.3
6.2.4	3	Containment Isolation System	13	Containment isolation using radiation monitors on system lines open to environs	FSAR	FSAR
6.2.4	3	Containment Isolation System	14	Isolation performance capability reflects safety importance	Conforms	6.2.4 15.5
6.2.4	3	Containment Isolation System	15	Closed system as isolation barrier	Conforms	6.2.4
6.2.4	3	Containment Isolation System	16	Reliability and performance of isolation barriers reflects safety importance	Conforms	6.2.4
6.2.4	3	Containment Isolation System	17	Isolation of remote-manual valves from Main Control Room (MCR)	Conforms	6.2.4 6.4
6.2.4	3	Containment Isolation System	18	Operability and leakage rate testing	Conforms	6.2.4
6.2.4	3	Containment Isolation System	19	Reopening isolation valves	Conforms	6.2.4
6.2.4	3	Containment Isolation System	20	Containment purging per 10 CFR 50.34(f)(2)(xv)	Conforms	Table 1.9-21

Table 1.9-6 Conformance with NUREG-0800 (Chapter 6 Engineered Safety Features)
(Sheet 8 of 13)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
6.2.4	3	Containment Isolation System	21	Guidance for meeting Station Blackout (SBO) rule, 10 CFR 50.63(a)(2)	Conforms	6.2.4
6.2.4	3	Containment Isolation System	22	Determination of fuel failure for radiological calculations	N/A – The ECCS evaluation model does not use the alternatives provided in 10 CFR Part 50 Appendix K.	N/A
6.2.5	3	Combustible Gas Control in Containment	1	Hydrogen generation and control	Conforms	6.2 3.8
6.2.5	3	Combustible Gas Control in Containment	2	Capability of non-inerted containments with regard to hydrogen generation	N/A – BWRX-300 containment is inerted.	N/A
6.2.5	3	Combustible Gas Control in Containment	3	Equipment survivability per 10 CFR 50.44(c)(3)	FSAR	FSAR
6.2.5	3	Combustible Gas Control in Containment	4	Mixed atmosphere	Conforms	6.2.5 9.3.6
6.2.5	3	Combustible Gas Control in Containment	5	RG 1.7, Rev 3, Section C.1	Conforms	Table 1.9-20
6.2.5	3	Combustible Gas Control in Containment	6	Performance tests and monitoring instrumentation to conform with GDC 41	Conforms	9.3.6
6.2.5	3	Combustible Gas Control in Containment	7	Inservice inspection, operability testing, leak rate testing to conform with GDC 41, 42, 43	Conforms	9.3.6

Table 1.9-6 Conformance with NUREG-0800 (Chapter 6 Engineered Safety Features)
(Sheet 9 of 13)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
6.2.5	3	Combustible Gas Control in Containment	8	Structural integrity with 100% clad-coolant reaction with combustible gas burning	FSAR	FSAR
6.2.5	3	Combustible Gas Control in Containment	9	Preliminary combustible gas control system design	Conforms	6.2.1 6.2.5 9.3.6
6.2.6	3	Containment Leakage Testing	All	Leakage rate testing, operational programs	Conforms	6.2.6
6.2.7	1	Fracture Prevention of Containment Pressure Boundary	1	Ferritic containment boundary materials	Conforms	3.8 6.2.7
6.2.7	1	Fracture Prevention of Containment Pressure Boundary	2	Ferritic containment boundary materials that have not been fracture toughness tested	N/A – This topic is not applicable as current fracture toughness requirements apply.	N/A
6.3	3	Emergency Core Cooling System	1	Performance criteria associated with 10 CFR 50.46	Conforms	6.3.3 15.3
6.3	3	Emergency Core Cooling System	2	Requirements of GDC 35 and GDC 17	Alternate Approach	3.1 6.3.3
6.3	3	Emergency Core Cooling System	3	Inservice inspection	Conforms	6.3.4
6.3	3	Emergency Core Cooling System	4	Combine reactivity control system capability to meet GDC 27	Conforms	3.1 6.3.3
6.3	3	Emergency Core Cooling System	5	RG 1.1	N/A – RG 1.1 has been withdrawn.	N/A

Table 1.9-6 Conformance with NUREG-0800 (Chapter 6 Engineered Safety Features)
(Sheet 10 of 13)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
6.3	3	Emergency Core Cooling System	6	Water hammer prevention per GDC 4	Conforms	6.3.3
6.3	3	Emergency Core Cooling System	7	Design of non safety-related portions to meet GDC 2	FSAR	FSAR
6.3	3	Emergency Core Cooling System	8	Interfaces between ECCS and shared systems	N/A – Does not interface with Service Water or other systems.	N/A
6.3	3	Emergency Core Cooling System	9	TMI Action Plan (NUREG-0737, NUREG-0718) requirements	N/A – High Pressure Coolant Injection, Reactor Core Isolation Cooling are not part of design.	N/A
6.3	3	Emergency Core Cooling System	10	ECCS outage times	FSAR	FSAR
6.4	3	Control Room Habitability	1	CR emergency zone	Alternate Approach	6.4 9.4.1 9.4.6
6.4	3	Control Room Habitability	2	Ventilation system criteria	Alternate Approach	6.4 9.4.1 9.4.6
6.4	3	Control Room Habitability	3	Pressurization systems	Alternate Approach	6.4 9.4.1 9.4.6
6.4	3	Control Room Habitability	4	Emergency standby atmospheric filtration systems conformance with RG 1.52	N/A – BWRX-300 design does not utilize an engineered safety feature ventilation system.	N/A

Table 1.9-6 Conformance with NUREG-0800 (Chapter 6 Engineered Safety Features)
(Sheet 11 of 13)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
6.4	3	Control Room Habitability	5	Relative location of source and CR	Alternate Approach	6.4 9.4 15.5
6.4	3	Control Room Habitability	6	Radiation hazards	Alternate Approach	6.4 15.5
6.4	3	Control Room Habitability	7	Toxic gas hazards	Alternate Approach	6.4 9.4
6.5.1	4	Engineered Safety Feature Atmosphere Cleanup Systems	II	Design, testing, and maintenance of ESF system	N/A – BWRX-300 design does not require an ESF containment atmospheric cleanup system. The CIS maintains an inert containment atmosphere.	N/A
6.5.2	4	Containment Spray as a Fission Product Cleanup System	N/A	Design requirements for fission product removal	N/A – BWRX-300 design does not include a containment spray system.	N/A
6.5.3	3	Fission Product Control Systems and Structures	1	Primary containment leak rate, containment isolation, potential doses	FSAR	FSAR
6.5.3	3	Fission Product Control Systems	2	Secondary containment	N/A – BWRX-300 design does not include a secondary containment.	N/A
6.5.3	3	Fission Product Control Systems and Structures	4	Other fission product control systems	N/A – BWRX-300 analysis does not credit other systems, filtration, or adsorption units.	N/A

Table 1.9-6 Conformance with NUREG-0800 (Chapter 6 Engineered Safety Features)
(Sheet 12 of 13)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
6.5.4	3	Ice Condenser as a Fission Product Cleanup System	N/A	Fission product removal effectiveness	N/A – BWRX-300 design does not include an ice condenser system.	N/A
6.5.5	1	Pressure Suppression Pool as a Fission Product Cleanup System	N/A	Fission product retention in suppression pool	N/A – BWRX-300 design does not incorporate a suppression pool.	N/A
6.6	2	Inservice Inspection and Testing of Class 2 and 3 Components	1	Components subject to inspection	Conforms	6.6.1 App 3A
6.6	2	Inservice Inspection and Testing of Class 2 and 3 Components	2	Accessibility for inspection	Conforms	6.6.2
6.6	2	Inservice Inspection and Testing of Class 2 and 3 Components	3	Examination categories and methods	Conforms	6.6.3
6.6	2	Inservice Inspection and Testing of Class 2 and 3 Components	4	Inspection intervals	Conforms	6.6.4
6.6	2	Inservice Inspection and Testing of Class 2 and 3 Components	5	Evaluation of examination results	Conforms	6.6.6
6.6	2	Inservice Inspection and Testing of Class 2 and 3 Components	6	System pressure tests	Conforms	6.6.8
6.6	2	Inservice Inspection and Testing of Class 2 and 3 Components	7	Augmented ISI to protect against piping failures	Conforms	6.6.9
6.6	2	Inservice Inspection and Testing of Class 2 and 3 Components	8	Code exemptions	Conforms	6.6.7
6.6	2	Inservice Inspection and Testing of Class 2 and 3 Components	9	Evaluation of relief requests per 10 CFR 50.55a	Conforms	6.6
6.6	2	Inservice Inspection and Testing of Class 2 and 3 Components	10	Exemptions from Code examination requirements permitted by Code cases	Conforms	6.6.7

Table 1.9-6 Conformance with NUREG-0800 (Chapter 6 Engineered Safety Features)
(Sheet 13 of 13)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
6.6	2	Inservice Inspection and Testing of Class 2 and 3 Components	11	Operational programs	FSAR	FSAR
6.7	2	Main Steam Isolation Valve Control System (BWR)	N/A	Main Steam Line valve leakage after LOCA	N/A – BWRX-300 design does not include a main steam isolation valve control system.	N/A
BTP 6-1	0	pH for Emergency Coolant water for Pressurized Water Reactors	N/A	pH of PWR containment sprays	N/A – BWR design	N/A
BTP 6-2	3	Minimum Containment Pressure Model for PWR ECCS Performance Evaluation	N/A	Containment pressure to evaluate PWR ECCS performance	N/A – BWR design	N/A
BTP 6-3	3	Determination of Bypass Leakage Paths in Dual Containment Plants	N/A	Bypass leakage from primary containment to environment	N/A – BWRX-300 design does not incorporate a dual containment.	N/A
BTP 6-4	3	Containment Purging During Normal Plant Operation	N/A	Containment purging during normal operation	N/A – BWRX-300 containment pressure is maintained by the CIS with temperature maintained by the CCS.	N/A
BTP 6-5	3	Currently the Responsibility of Reactor Systems Piping from the Refueling Water Storage Tank (RWST) (or BWST) and Containment Sump(s) to the Safety Injection Pumps	N/A	PWR use of RWST (or BWST) and pumps to provide ECCS injection	N/A – BWRX-300 design does not include ECCS injection pumps.	N/A

Table 1.9-7 Conformance with Design Review Guide (Chapter 7 Instrumentation and Controls)

See Table 7.3-5, Table 7.3-6, Table 7.3-7, and Table 7.3-8 for how the BWRX-300 design meets the DRG based on the Safety Classification.

Table 1.9-8 Conformance with NUREG-0800 (Chapter 8 Electric Power)
(Sheet 1 of 7)

SRP Section	Rev	Title	Criterion	Topic	Conformance	PSAR Section
8.1	4	Electric Power-Introduction	II	Reference to other sections for specific acceptance criteria	Conforms	8.1
8.2	5	Offsite Power System	1	Withstanding effects of natural phenomena per GDC 2 requirements	Conforms	8.1.3 8.2.1
8.2	5	Offsite Power System	2	Protection against dynamic effects, including missiles generated from equipment failure per GDC 4 requirements	Conforms	8.1.3 8.2.1
8.2	5	Offsite Power System	3	Sharing of SSCs at multi-unit stations per GDC 5 requirements	N/A – CRN-1 application is for a single unit.	N/A
8.2	5	Offsite Power System	4	Capability, capacity, availability of preferred power source per GDC 17 requirements	N/A – Offsite power is not required for accident mitigation.	N/A
8.2	5	Offsite Power System	5	Inspection and testing per GDC 18 requirements	Conforms	8.1.3
8.2	5	Offsite Power System	6	Operation per GDCs 34, 38, 41, and 44 requirements	N/A – Offsite power system not required for accident mitigation.	N/A
8.2	5	Offsite Power System	7	Alternate AC power source per 10 CFR 50.63 requirements	N/A – BWRX-300 design is a passive design with a 72-hour coping capability.	N/A
8.2	5	Offsite Power System	8	Maintenance per 10 CFR 50.65 requirements	FSAR	FSAR

Table 1.9-8 Conformance with NUREG-0800 (Chapter 8 Electric Power)

Note 1: Regulatory Guide 1.70, Standard Format and Content of Safety Analysis Reports for Nuclear Power Plants, Rev. 3, does not require a description of the Reliability Assurance Program in the PSAR. 10 CFR 50.34, Contents of applications; technical information, does not require a description of the Reliability Assurance Program. There is no specific requirement or associated guidance for inclusion of a RAP in a 10 CFR Part 50 construction permit. However, since TVA intends to comply with SRP 17.4 for FSAR, information pertinent to how the program is being established and implemented is being included in the PSAR. Programmatic information, including PRA risk-significant criteria, are included so that USNRC staff understand how the D-RAP is being developed. Additional information, including the list of D-RAP SSCs, will be included in the FSAR.

Table 1.9-21 Compliance with Three Mile Island Requirements (10 CFR 50.34(f))
(Sheet 1 of 16)

Regulation	Description	Compliance	Comments	PSAR Section
50.34(f)(1)(i)	Perform a plant/site-specific probabilistic risk assessment, the aim of which is to seek such improvements in the reliability of core and containment heat removal systems as are significant and practical and do not impact excessively on the plant (II.B.8)	FSAR		FSAR
50.34(f)(1)(ii)	Perform an evaluation of the proposed Auxiliary Feedwater System (applicable to PWRs only) (II.E.1.1)	N/A	The regulation is only applicable to PWR designs.	N/A
50.34(f)(1)(iii)	Perform an evaluation of the potential for and impact of reactor coolant pump seal damage following small-break LOCA with loss of offsite power. If damage cannot be precluded, provide an analysis of the limiting small-break loss-of-coolant accident with subsequent reactor coolant pump seal damage. (II.K.2.16 and II.K.3.25)	N/A	Not technically relevant to the BWRX-300. The BWRX-300 design does not have reactor cooling pumps.	N/A
50.34(f)(1)(iv)	Perform an analysis of the probability of a small-break LOCA caused by a stuck-open Power Operated Relief Valve (PORV). If this probability is a significant contributor to the probability of small-break LOCAs from all causes, provide a description and evaluation of the effect on small-break LOCA probability of an automatic PORV isolation system that would operate when the reactor coolant system pressure falls after the PORV has opened. (Applicable to PWR's only). (II.K.3.2)	N/A	The regulation is only applicable to PWR designs.	N/A

Table 1.9-21 Compliance with Three Mile Island Requirements (10 CFR 50.34(f))
(Sheet 2 of 16)

Regulation	Description	Compliance	Comments	PSAR Section
50.34(f)(1)(v)	Perform an evaluation of the safety effectiveness of providing for separation of high pressure coolant injection and Reactor Core Isolation Cooling (RCIC) system initiation levels so that the RCIC system initiates at a higher water level than the high pressure coolant injection system, and of providing that both systems restart on low water level. (For plants with high pressure core spray systems in lieu of high pressure coolant injection systems, substitute the words, high pressure core spray for high pressure coolant injection and HPCS for HPCI) (Applicable to BWR's only). (II.K.3.13)	N/A	Not technically relevant to the BWRX-300. The BWRX-300 is a passive design and only credits the Isolation Condenser System (ICS). The BWRX-300 design does not include a RCIC system.	N/A
50.34(f)(1)(vi)	Perform a study to identify practicable system modifications that would reduce challenges and failures of relief valves, without compromising the performance of the valves or other systems. (Applicable to BWR's only). (II.K.3.16)	N/A	Not technically relevant to the BWRX-300. The design features of the BWRX-300 RCPB include the use of the I&C System and ICS for overpressure protection, and relief and safety valves are not required and are not included in the design to meet the overpressure protection acceptance criteria.	N/A

Table 1.9-21 Compliance with Three Mile Island Requirements (10 CFR 50.34(f))
(Sheet 3 of 16)

Regulation	Description	Compliance	Comments	PSAR Section
50.34(f)(1)(vii)	Perform a feasibility and risk assessment study to determine the optimum Automatic Depressurization System (ADS) design modifications that would eliminate the need for manual activation to ensure adequate core cooling. (Applicable to BWR's only). (II.K.3.18)	N/A	Not technically relevant to the BWRX-300. Automatic actuation of RPV isolation along with automatic actuation of the ICS performs the function to mitigate the effects of a LOCA.	N/A
50.34(f)(1)(viii)	Perform a study of the effect on all core-cooling modes under accident conditions of designing the core spray and low pressure coolant injection systems to ensure that the systems will automatically restart on loss of water level, after having been manually stopped, if an initiation signal is still present. (Applicable to BWR's only). (II.K.3.21)	N/A	Not technically relevant to the BWRX-300.The BWRX-300 is a passive design and only credits the ICS.	N/A
50.34(f)(1)(ix)	Perform a study to determine the need for additional space cooling to ensure reliable long-term operation of the RCIC and high-pressure coolant injection systems, following a complete loss of offsite power to the plant for at least two (2) hours. (For plants with high pressure core spray systems in lieu of high pressure coolant injection systems, substitute the words, high pressure core spray for high pressure coolant injection and HPCS for HPCI) (Applicable to BWR's only). (II.K.3.24)	N/A	Not technically relevant to the BWRX-300. The BWRX-300 does not include RCIC and High Pressure Coolant Injection systems, because automatic actuation of RPV isolation along with automatic actuation of the ICS are sufficient to mitigate the effects of a LOCA.	N/A

Table 1.9-21 Compliance with Three Mile Island Requirements (10 CFR 50.34(f))
(Sheet 4 of 16)

Regulation	Description	Compliance	Comments	PSAR Section
50.34(f)(1)(x)	Perform a study to ensure that the Automatic Depressurization System, valves, accumulators, and associated equipment and instrumentation will be capable of performing their intended functions during and following an accident situation, taking no credit for non-safety related equipment or instrumentation, and accounting for normal expected air (or nitrogen) leakage through valves. (Applicable to BWR's only). (II.K.3.28)	N/A	Not technically relevant to the BWRX-300. The BWRX-300 does not include an ADS because automatic actuation of RPV isolation along with automatic actuation of the ICS are sufficient without the need to blowdown the RCS to a suppression pool either automatically or manually to mitigate the effects of a LOCA.	N/A
50.34(f)(1)(xi)	Provide an evaluation of depressurization methods, other than by full actuation of the automatic depressurization system, that would reduce the possibility of exceeding vessel integrity limits during rapid cooldown. (Applicable to BWR's only) (II.K.3.45)	N/A	Not technically relevant to the BWRX-300. The BWRX-300 is a passive design and only credits the ICS.	N/A
50.34(f)(1)(xii)	Perform an evaluation of alternative hydrogen control systems that would satisfy the requirements of paragraph (f)(2)(ix) of this section. As a minimum include consideration of a hydrogen ignition and post-accident inerting system	Complies		6.3.3
50.34(f)(2)(i)	Provide simulator capability that correctly models the control room and includes the capability to simulate small-break LOCAs. (Applicable to construction permit applicants only) (I.A.4.2.)	FSAR		FSAR

Table 1.9-21 Compliance with Three Mile Island Requirements (10 CFR 50.34(f))
(Sheet 5 of 16)

Regulation	Description	Compliance	Comments	PSAR Section
50.34(f)(2)(ii)	Establish a program, to begin during construction and follow into operation, for integrating and expanding current efforts to improve plant procedures. The scope of the program shall include emergency procedures, reliability analyses, human factors engineering, crisis management, operator training, and coordination with Institute of Nuclear Power Operations (INPO) and other industry efforts. (Applicable to construction permit applicants only) (I.C.9)	FSAR		FSAR
50.34(f)(2)(iii)	Provide, for Commission review, a control room design that reflects state-of-the-art human factor principles prior to committing to fabrication or revision of fabricated control room panels and layouts. (I.D.1)	FSAR		FSAR
50.34(f)(2)(iv)	Provide a plant safety parameter display console that will display to operators a minimum set of parameters defining the safety status of the plant, capable of displaying a full range of important plant parameters and data trends on demand, and capable of indicating when process limits are being approached or exceeded. (I.D.2)	Complies		7.1.3
50.34(f)(2)(v)	Provide for automatic indication of the bypassed and operable status of safety systems. (I.D.3)	Complies		7.1.3 8.1.3

Table 1.9-21 Compliance with Three Mile Island Requirements (10 CFR 50.34(f))
(Sheet 6 of 16)

Regulation	Description	Compliance	Comments	PSAR Section
50.34(f)(2)(vi)	Provide the capability of high point venting of noncondensible gases from the reactor coolant system, and other systems that may be required to maintain adequate core cooling. Systems to achieve this capability shall be capable of being operated from the CR and their operation shall not lead to an unacceptable increase in the probability of loss-of-coolant accident or an unacceptable challenge to containment integrity. (II.B.1)	N/A	Not technically relevant to the BWRX-300. The intent of this requirement is met by the configuration of the ICS piping and purge capability, which controls potential accumulation of non-condensable gases that could affect ECCS function.	N/A
50.34(f)(2)(vii)	Perform radiation and shielding design reviews of spaces around systems that may, as a result of an accident, contain accident source term radioactive materials, and design as necessary to permit adequate access to important areas and to protect safety equipment from the radiation environment. (II.B.2)	FSAR		FSAR
50.34(f)(2)(viii)	Provide a capability to promptly obtain and analyze samples from the reactor coolant system and containment that may contain accident source term radioactive materials without radiation exposures to any individual exceeding 5 rems to the whole body or 50 rems to the extremities. Materials to be analyzed and quantified include certain radionuclides that are indicators of the degree of core damage (e.g., noble gases, radioiodines and cesiums, and nonvolatile isotopes), hydrogen in the containment atmosphere, dissolved gases, chloride, and boron concentrations. (II.B.3)	FSAR		FSAR

Table 1.9-21 Compliance with Three Mile Island Requirements (10 CFR 50.34(f))
(Sheet 7 of 16)

Regulation	Description	Compliance	Comments	PSAR Section
50.34(f)(2)(ix)	Provide a system for hydrogen control that can safely accommodate hydrogen generated by the equivalent of a 100% fuel-clad metal water reaction. Preliminary design information on the tentatively preferred system option of those being evaluated in paragraph (f)(1)(xii) of this section is sufficient at the construction permit stage.	Complies		6.2.1
50.34(f)(2)(x)	Provide a test program and associated model development and conduct tests to qualify reactor coolant system relief and safety valves and, for PWR's, PORV block valves, for all fluid conditions expected under operating conditions, transients, and accidents. Consideration of Anticipated Transients Without Scram (ATWS) conditions shall be included in the test program. Actual testing under ATWS conditions need not be carried out until subsequent phases of the test program are developed. (II.D.1)	N/A	Not technically relevant to the BWRX-300. The design features of the BWRX-300 RCPB include the use of the I&C System and ICS for overpressure protection, and relief and safety valves are not required and are not included in the design to meet the overpressure protection acceptance criteria.	N/A
50.34(f)(2)(xi)	Provide direct indication of relief and safety valve position (open or closed) in the control room. (II.D.3)	N/A	Not technically relevant to the BWRX-300. The BWRX-300 design does not have traditional relief valves. The need for the direct indication is based on monitoring open relief valves for reactor coolant loss. This issue is not applicable to the closed system ICS used for overpressure protection.	N/A

Table 1.9-21 Compliance with Three Mile Island Requirements (10 CFR 50.34(f))
(Sheet 8 of 16)

Regulation	Description	Compliance	Comments	PSAR Section
50.34(f)(2)(xii)	Provide automatic and manual auxiliary feedwater (AFW) system initiation and provide auxiliary feedwater system flow indication in the control room. (Applicable to PWR's only) (II.E.1.2)	N/A	The regulation is only applicable to PWR designs.	N/A
50.34(f)(2)(xiii)	Provide pressurizer heater power supply and associated motive and control power interfaces sufficient to establish and maintain natural circulation in hot standby conditions with only onsite power available. (Applicable to PWR's only) (II.E.3.1)	N/A	The regulation is only applicable to PWR designs.	N/A
50.34(f)(2)(xiv)	Provide containment isolation systems (II.E.4.2)	Complies		6.2.4 7.1.3
50.34(f)(2)(xv)	Provide a capability for containment purging/venting designed to minimize the purging time consistent with ALARA principles for occupational exposure. Provide and demonstrate high assurance that the purge system will reliably isolate under accident conditions. (II.E.4.4)	Complies		6.2.1 6.2.4
50.34(f)(2)(xvi)	Establish a design criterion for the allowable number of actuation cycles of the emergency core cooling system and Reactor Protection System consistent with the expected occurrence rates of severe overcooling events (considering both anticipated transients and accidents). (Applicable to B&W designs only). (II.E.5.1)	N/A	The regulation is only applicable to B&W designs.	N/A

Table 1.9-21 Compliance with Three Mile Island Requirements (10 CFR 50.34(f))
(Sheet 9 of 16)

Regulation	Description	Compliance	Comments	PSAR Section
50.34(f)(2)(xvii)	Provide instrumentation to measure, record, and readout in the control room: (A) containment pressure, (B) containment water level, (C) containment hydrogen concentration, (D) containment radiation intensity (high level), and (E) noble gas effluents at all potential, accident release points. Provide for continuous sampling of radioactive iodines and particulates in gaseous effluents from all potential accident release points, and for onsite capability to analyze and measure these samples. (II.F.1)	Complies		6.2.1.3 6.8 7.1.3 7.3.1 12.3.4
50.34(f)(2)(xviii)	Provide instruments that provide in the control room an unambiguous indication of inadequate core cooling, such as primary coolant saturation meters in PWR's, and a suitable combination of signals from indicators of coolant level in the reactor vessel and in-core thermocouples in PWR's and BWR's. (II.F.2)	FSAR	The design of the instrumentation to show compliance will be discussed in the FSAR.	FSAR
50.34(f)(2)(xix)	Provide instrumentation adequate for monitoring plant conditions following an accident that includes core damage. (II.F.3)	Complies		6.8 7.1.3 7.3.1

Table 1.9-21 Compliance with Three Mile Island Requirements (10 CFR 50.34(f))
(Sheet 10 of 16)

Regulation	Description	Compliance	Comments	PSAR Section
50.34(f)(2)(xx)	Provide power supplies for pressurizer relief valves, block valves, and level indicators such that: (A) Level indicators are powered from vital buses; (B) motive and control power connections to the emergency power sources are through devices qualified in accordance with requirements applicable to systems important to safety and (C) electric power is provided from emergency power sources. (Applicable to PWR's only). (II.G.1)	N/A	The regulation is only applicable to PWR designs.	N/A
50.34(f)(2)(xxi)	Design auxiliary heat removal systems such that necessary automatic and manual actions can be taken to ensure proper functioning when the main feedwater system is not operable. (Applicable to BWR's only). (II.K.1.22)	Complies		6.3.3
50.34(f)(2)(xxii)	Perform a failure modes and effects analysis of the integrated control system to include consideration of failures and effects of input and output signals to the ICS. (Applicable to B&W-designed plants only). (II.K.2.9)	N/A	The regulation is only applicable to B&W designs.	N/A
50.34(f)(2)(xxiii)	Provide, as part of the reactor protection system, an anticipatory reactor trip that would be actuated on loss of main feedwater and on turbine trip. (Applicable to B&W-designed plants only). (II.K.2.10)	N/A	The regulation is only applicable to B&W designs.	N/A
50.34(f)(2)(xxiv)	Provide the capability to record reactor vessel water level in one location on recorders that meet normal post-accident recording requirements. (Applicable to BWR's only). (II.K.3.23)	Complies		7.1.3 7.3.1

Table 1.9-21 Compliance with Three Mile Island Requirements (10 CFR 50.34(f))
(Sheet 11 of 16)

Regulation	Description	Compliance	Comments	PSAR Section
50.34(f)(2)(xxv)	Provide an onsite Technical Support Center, an onsite Operational Support Center, and, for construction permit applications only, a nearsite Emergency Operations Facility. (III.A.1.2).	FSAR		FSAR
50.34(f)(2)(xxvi)	Provide for leakage control and detection in the design of systems outside containment that contain (or might contain) accident source term radioactive materials following an accident. Applicants shall submit a leakage control program, including an initial test program, a schedule for re-testing these systems, and the actions to be taken for minimizing leakage from such systems. The goal is to minimize potential exposures to workers and public, and to provide reasonable assurance that excessive leakage will not prevent the use of systems needed in an emergency. (III.D.1.1)	Complies		5.4.7 6.2.1 6.3.3
50.34(f)(2)(xxvii)	Provide for monitoring of in-plant radiation and airborne radioactivity as appropriate for a broad range of routine and accident conditions. (III.D.3.3)	Complies		12.3.4
50.34(f)(2)(xxviii)	Evaluate potential pathways for radioactivity and radiation that may lead to control room habitability problems under accident conditions resulting in an accident source term release and make necessary design provisions to preclude such problems. (III.D.3.4)	Complies		6.4.3

Table 1.9-21 Compliance with Three Mile Island Requirements (10 CFR 50.34(f))
(Sheet 12 of 16)

Regulation	Description	Compliance	Comments	PSAR Section
50.34(f)(3)(i)	Provide administrative procedures for evaluating operating, design, and construction experience and for ensuring that applicable important industry experiences will be provided in a timely manner to those designing and constructing the plant. (I.C.5)	FSAR		FSAR
50.34(f)(3)(ii)	Ensure that the quality assurance (QA) list required by Criterion II, app. B, 10 CFR part 50 includes all structures, systems, and components important to safety. (I.F.1)	Complies		13.2 13.4 17.5
50.34(f)(3)(iii)	Establish a quality assurance (QA) program based on consideration of: (A) Ensuring independence of the organization performing checking functions from the organization responsible for performing the functions; (B) performing quality assurance/quality control functions at construction sites to the maximum feasible extent; (C) including QA personnel in the documented review of and concurrence in quality related procedures associated with design, construction and installation; (D) establishing criteria for determining QA programmatic requirements; (E) establishing qualification requirements for QA and QC personnel; (F) sizing the QA staff commensurate with its duties and responsibilities; (G) establishing procedures for maintenance of as-built documentation; and (H) providing a QA role in design and analysis activities. (I.F.2)	Complies		13.2 13.4 17.5

Table 1.9-21 Compliance with Three Mile Island Requirements (10 CFR 50.34(f))
(Sheet 13 of 16)

Regulation	Description	Compliance	Comments	PSAR Section
50.34(f)(3)(iv)	Provide one or more dedicated containment penetrations, equivalent in size to a single 3-foot diameter opening, in order not to preclude future installation of systems to prevent containment failure, such as a filtered vented containment system. (II.B.8)	FSAR		FSAR

Table 1.9-21 Compliance with Three Mile Island Requirements (10 CFR 50.34(f))
(Sheet 14 of 16)

Regulation	Description	Compliance	Comments	PSAR Section
50.34(f)(3)(v)(A)(1)	Containment integrity will be maintained (i.e., for steel containments by meeting the requirements of the ASME Boiler and Pressure Vessel Code, Section III, Division 1, subarticle NE-3220, Service Level C Limits, except that evaluation of instability is not required, considering pressure and dead load alone. For concrete containments by meeting the requirements of the ASME Boiler Pressure Vessel Code, Section III, Division 2 subarticle CC-3720, Factored Load Category, considering pressure and dead load alone) during an accident that releases hydrogen generated from 100% fuel clad metal-water reaction accompanied by either hydrogen burning or the added pressure from post-accident inerting assuming carbon dioxide is the inerting agent. As a minimum, the specific code requirements set forth above appropriate for each type of containment will be met for a combination of dead load and an internal pressure of 45 psig. Modest deviations from these criteria will be considered by the staff, if good cause is shown by an applicant. Systems necessary to ensure containment integrity shall also be demonstrated to perform their function under these conditions.	FSAR		FSAR

Table 1.9-21 Compliance with Three Mile Island Requirements (10 CFR 50.34(f))
(Sheet 15 of 16)

Regulation	Description	Compliance	Comments	PSAR Section
50.34(f)(3)(v)(B)(1)	(B)(1) Containment structure loadings produced by an inadvertent full actuation of a post-accident inerting hydrogen control system (assuming carbon dioxide), but not including seismic or design basis accident loadings will not produce stresses in steel containments in excess of the limits set forth in the ASME Boiler and Pressure Vessel Code, Section III, Division 1, subarticle NE3220, Service Level A Limits, except that evaluation of instability is not required (for concrete containments the loadings specified above will not produce strains in the containment liner in excess of the limits set forth in the ASME Boiler and Pressure Vessel Code, Section III, Division 2, subarticle CC-3720, Service Load Category.	FSAR		FSAR
50.34(f)(3)(v)(B)(2)	(2) The containment has the capability to safely withstand pressure tests at 1.10 and 1.15 times (for steel and concrete containments, respectively) the pressure calculated to result from carbon dioxide inerting.	N/A	Not technically relevant to the BWRX-300. The BWRX-300 design does not inert with carbon dioxide.	N/A
50.34(f)(3)(vi)	For plant designs with external hydrogen recombiners, provide redundant dedicated containment penetrations so that, assuming a single failure, the recombiner systems can be connected to the containment atmosphere. (II.E.4.1)	N/A	Not technically relevant to the BWRX-300. The BWRX-300 does not include external recombiners.	N/A

Table 1.9-21 Compliance with Three Mile Island Requirements (10 CFR 50.34(f))
(Sheet 16 of 16)

Regulation	Description	Compliance	Comments	PSAR Section
50.34(f)(3)(vii)	Provide a description of the management plan for design and construction activities, to include: (A) The organizational and management structure singularly responsible for direction of design and construction of the proposed plant; (B) technical resources director by the applicant; (C) details of the interaction of design and construction within the applicant's organization and the manner by which the applicant will ensure close integration of the architect engineer and the nuclear steam supply vendor; (D) proposed procedures for handling the transition to option; (E) the degree of top level management oversight and technical control to be exercised by the applicant during design and construction, including the preparation and implementation of procedures necessary to guide the effort. (II.J.3.1)	Complies		1.4

1.10 Nuclear Power Plants to Be Operated on Multi-Unit Site

CRN-1 is not co-located at the CRN Site with an existing nuclear plant or a nuclear plant under construction. Thus, there are no construction hazards associated with co-located units.

CHAPTER 2 SITE CHARACTERISTICS AND SITE PARAMETERS

Chapter 2 of the referenced ESPA SSAR is incorporated by reference with the following supplements.

Replace the first paragraph with the following:

Chapter 2 of the PSAR describes the characteristics of the Clinch River Nuclear (CRN) Site, including site related parameters for the CRN-1 Plant and the geological, seismological, hydrological, and meteorological characteristics of the site and vicinity. The CRN Site location, characteristics, and site-related design parameters, as described in the following sections, are provided in sufficient detail to support a safety assessment:

Section 2.0: Plant Parameter Envelope Evaluation

Section 2.1: Geography and Demography

Section 2.2: Nearby Industrial, Transportation, and Military Facilities

Section 2.3: Meteorology

Section 2.4: Hydrologic Engineering

Section 2.5: Geology, Seismology, and Geotechnical Engineering

2.0 Plant Parameter Envelope Evaluation

Replace ESPA SSAR Section 2.0 with the following:

TVA selected the GEH BWRX-300 small modular reactor (SMR) for deployment at the CRN Site. The site suitability of the CRN Site is established in the Early Site Permit Application. Evaluation of the BWRX-300 design parameters as compared to the CRN Site ESPA is provided in this section. In support of this safety assessment, Table 2.0-1R provides a comparison of site-related design parameters for which the BRWX-300 SMR is designed to the site characteristics specific of CRN-1. The first four columns of Table 2.0-1R are a compilation of site characteristics for CRN-1. The last two columns of Table 2.0-1R contain information for the corresponding BWRX-300 SMR site parameter. Table 2.0-2R provides a comparison of site-related design parameters for which the BRWX-300 SMR is designed to the site related design specific for CRN-1 in support of this safety assessment. The first four columns of Table 2.0-2R are a compilation of site related design parameters for CRN-1. The last two columns of Table 2.0-2R contain information for the corresponding BWRX-300 SMR site parameter. Table 2.0-3R through Table 2.0-6R provide a comparison of releases for the BWRX-300 SMR from: LOCA Design Basis Accident, Annual Normal Gaseous Radioactive Release, Accidental Liquid Radwaste Release and Annual Normal Liquid Radioactive Release, respectively.

Add new Section 2.0.1:

2.0.1 Justification of Exceedances

As shown in Table 2.0-1R and Table 2.0-2R, the Site Characteristics and the Site Related Design Parameters for CRN-1 are bounded by those developed for the ESPA Plant Parameter Envelope (PPE) except for the single unit thermal megawatts value of 800 MWt. The BWRX-300 SMR design has an 870 MWt nominal output. The 70 MWt exceedance for a single unit is acceptable for the CRN Site because as shown in the PPE comparison tables provided in this section, all other Clinch River ESP-006 PPE performance requirements (radiological release, structural design, etc.) are met for both the site and a single unit.

Justifications for the CRN-1 exceedances for the remaining release data are provided below:

LOCA: Design basis accidents for the GEH BWRX-300 SMR are evaluated in Chapter 15. The Feedwater Line Break Accident is the most limiting DBA. Releases for several radionuclides for the FWLB accident exceed the release in the LOCA DBA evaluated in the CRN ESP SSAR as shown in Table 2.0-3R. However, the dose consequence of the postulated FWLB accident (Table 15.7-6) is below applicable acceptance criteria and therefore the exceedances shown in Table 2.0-3R are acceptable.

Annual Normal Gaseous Radioactive Release: Releases for several radionuclides for Annual Normal Gaseous Radioactive Release exceed the release evaluated in the ESPA SSAR as shown in Table 2.0-4R. As described in Table 2.0-4R footnotes, the exceedances have been evaluated and show that CRN-1 calculated site boundary concentration limits and offsite receptor annual average doses are bounded by values presented in ESPA SSAR Table 11.2-7, and Tables 11.3-3 through 11.3-5; and remain within regulatory limits.

Accidental Liquid Radwaste Release: Releases for several radionuclides for the Accidental Liquid Radwaste Release accident exceed the release evaluated in the ESPA SSAR as shown in Table 2.0-5R. However, the dose consequence of the postulated Accidental Liquid Radwaste Release (Section 2.4.13.8) is less than the 10 CFR 20.1301 limit of 100 mrem TEDE and therefore the exceedances shown in Table 2.0-5R are acceptable.

Annual Normal Liquid Radioactive Release: Releases for several radionuclides for Annual Normal Liquid Radioactive Release exceed the release evaluated in the ESPA SSAR as shown in Table 2.0-6R. The specific radionuclides that exceed ESPA PPE are minor dose contributors with respect to the considered dominant dose contributing radionuclides. The dominant dose contributing radionuclides (e.g., I-131, Cs-137, and H-3) calculated for CRN-1 are exceeded by many orders of magnitude by the corresponding ESPA PPE values. Therefore, the normal operation dose consequence from liquid effluents to members of the public from CRN-1 is expected to be bounded by ESPA PPE.

Replace Table 2.0-1 with the following:

Table 2.0-1R Site Characteristics
(Sheet 1 of 8)

Characteristic/ Parameter	PPE Site-Specific Value	Description	ESPA SSAR Section	CRN Site-Related Design Parameter	Comments
Geography and Demography					
EAB	Clinch River Property Boundary	The area surrounding the reactors, in which the reactor licensee has the authority to determine all activities, including exclusion or removal of personnel and property from the area.	2.1.1	Clinch River Property Boundary	Design parameter equals Site-Specific Value.
LPZ	1 mi from CRN Site center point	The area immediately surrounding the exclusion area which contains residents, the total number and density of which are such that there is a reasonable probability that appropriate protective measures could be taken in their behalf in the event of a serious accident.	2.1.3.4	1 mi from CRN Site center point	Design parameter equals Site-Specific Value.
Population Center Distance	4.8 mi (southeast)	The distance from the site center point to the nearest boundary of a densely populated center containing more than about 25,000 residents.	2.1.3.5	4.8 mi (southeast)	Design parameter equals Site-Specific Value.
Meteorology and Hydrology					
Winter Precipitation					
Normal Winter Precipitation Event	21.9 psf	The maximum ground-level weight (lb/ft^2) of the 1) 100-year return snowpack (snow cover), 2) historical snowpack (snow cover), 3) 100-year-return 2-day snowfall event, or 4) historical maximum 2-day snowfall event.	2.3.1.3.6.2	52.2 psf	Design parameter bounds Site-Specific Value.
Extreme Frozen Winter Precipitation Event	21.9 psf	The maximum ground-level weight (lb/ft^2) of the 1) 100-year return 2-day snowfall event or 2) historical maximum 2-day snowfall event.	2.3.1.3.6.2	104 psf	Design parameter bounds Site-Specific Value.

Table 2.0-1R Site Characteristics
(Sheet 2 of 8)

Characteristic/ Parameter	PPE Site-Specific Value	Description	ESPA SSAR Section	CRN Site-Related Design Parameter	Comments
Extreme Liquid Winter Precipitation Event (48-hour Probable Maximum Winter Precipitation)	23.5 in	The extreme liquid winter precipitation event is defined as the theoretically greatest ground-level depth of precipitation (in inches of water) for a 48-hour period that is physically possible over a 25.9 square kilometer (10 square mile) area at a particular geographical location during those months with the historically highest snowpacks.	2.3.1.3.6.2	N/A	Not relevant to BWRX-300 design.
Potential for Frazil Ice in Ultimate Heat Sink Water Storage Facility	N/A	Potential for accumulated ice formation in the Ultimate Heat Sink Water Storage Facility in a turbulent flow condition.	2.4.7	N/A	Same as ESPA PPE.
Maximum Rainfall Rate	18.8 in/hr 6 in/5 minutes	Probable Maximum Precipitation for 1-hour and for 5-minute durations at the site estimated from Hydro-Meteorological Report HMR-52.	2.3.1.3.3	19.4 in/hr 6.2 in/5 minutes.	Design parameter bounds Site-Specific Value.
Maximum Flood (or Tsunami)	[ ]	Predicted maximum flood level (including wave run-up) from external events, not including local Probable Maximum Precipitation.	2.4.2, 2.4.3, and 2.4.10	[ ]	The maximum flood level is below the design plant grade level.
Maximum Ground Water	816.1 ft NAVD88	Maximum groundwater level under deep foundation structures in power block area.	2.4.12	At plant grade (814.5 ft NAVD88)	Maximum ground water will be at plant grade.
Basic Wind Speed	96.3 mph for a 3-second gust	Wind velocity at 33 ft above ground for Exposure Category C associated with a 100-year return period in the site area.	2.3.1.3.2	160 mph	Design parameter bounds Site-Specific Value.
Historical Maximum Wind Speed	87 mph for a 3-second gust 73 mph fastest mile	Wind velocity at 33 ft above ground associated with the most severe hurricane wind that has been historically observed in the site region.	2.3.1.3.2	N/A	Not relevant to BWRX-300 design.
Design-Basis Hurricane Windspeed	130 mph for a 3-second gust	The resulting windspeed for nominal 3-second peak-gust values at a height of 33 ft in flat open terrain.	2.3.1.3.5	200 mph	Design parameter bounds Site-Specific Value.

Table 2.0-1R Site Characteristics
(Sheet 3 of 8)

Characteristic/ Parameter	PPE Site-Specific Value	Description	ESPA SSAR Section	CRN Site-Related Design Parameter	Comments
Tornado					
Maximum Pressure Drop	1.2 psi	Decrease in ambient pressure from normal atmospheric pressure at the site due to passage of a tornado having a probability of occurrence of 10^{-7} per year.	2.3.1.3.4	1.2 psi	Design parameter equals Site-Specific Value.
Maximum Rotational Speed	184 mph	Rotation component of maximum wind speed at the site due to passage of a tornado having a probability of occurrence of 10^{-7} per year.	2.3.1.3.4	184 mph	Design parameter equals Site-Specific Value.
Maximum Translational Speed	46 mph	Translation component of maximum wind speed at the site due to the movement across the ground of a tornado having a probability of occurrence of 10^{-7} per year.	2.3.1.3.4	46 mph	Design parameter equals Site-Specific Value.
Maximum Wind Speed	230 mph	Sum of the maximum rotational and translational wind speed components at the site due to passage of a tornado having a probability of occurrence of 10^{-7}per year.	2.3.1.3.4	230 mph	Design parameter equals Site-Specific Value.
Radius of Maximum Rotational Speed	150 ft	Distance from the center of the tornado at which the maximum rotational wind speed occurs at site due to passage of a tornado having a probability of occurrence of 10^{-7} per year.	2.3.1.3.4	150 ft	Design parameter equals Site-Specific Value.
Rate of Pressure Drop	0.5 psi/s	Maximum rate of pressure drop at site due to passage of a tornado having a probability of occurrence of 10^{-7} per year.	2.3.1.3.4	0.5 psi/s	Design parameter equals Site-Specific Value.

Liquid Releases					
Dose Consequences					
Normal	10 CFR 20, App. B 10 CFR 50, App. I	Estimated design radiological dose consequences due to liquid releases from normal operation of the plant.	11.2.3	10 CFR 50 APP I 10 CFR 20 Appendix B	These are the dose related limits for normal release effluents.
Post-Accident	10 CFR 20, App. B DC/COL-ISG-013	Estimated design radiological dose consequences due to liquid releases from postulated accidents.	2.4.13	NUREG-0800, BTP 11-6	These are the accident dose limits.
Geology, Seismology, and Geotechnical Engineering					
Ground Motion Response Spectra	Refer to ESPA SSAR Figure 2.5.2-78	The design response spectra used to establish a plant's seismic design	2.5.2	Same as ESPA PPE.	Design parameter equals Site-Specific Value.
Capable Tectonic Structures or Sources	None	The assumption made in a plant design about the presence of capable faults or earthquake sources in the vicinity of the plant site (e.g., no fault displacement potential within the investigative area).		No fault displacement within the site area, no permanent ground deformation per 10 CFR 100.23.	The site condition meets the design requirements for the BWRX-300.
Soil Properties					
Liquefaction	None	Liquefaction potential at the site.	2.5.4	None under footprint of Seismic Cat I structures from Site-Specific SSE	The site condition meets the design requirements for the BWRX-300.
Minimum Bearing Capacity	110 ksf (static)	Allowable load-bearing capacity of layer supporting plant structures.	2.5.4	Total minimum bearing capacity (static and dynamic) 33.4 ksf	Design parameter bounds Site-Specific Value.
Minimum Shear Wave Velocity	4650 ft/s	Propagation velocity of shear waves through foundation materials.	2.5.4	~1000 ft/s (300 m/s) (below Seismic Cat I foundations)	Design parameter bounds Site-Specific Value.
Dynamic Bearing Capacity	110 ksf	Capacity of the foundation soil/rock to resist loads imposed by the structures in the event of an earthquake.	2.5.4	Total minimum bearing capacity (static and dynamic) 33.4 ksf	Design parameter bounds Site-Specific Value.

Table 2.0-1R Site Characteristics
(Sheet 8 of 8)

Characteristic/ Parameter	PPE Site-Specific Value	Description	ESPA SSAR Section	CRN Site-Related Design Parameter	Comments
Minimum Soil Angle of Internal Friction	36°	Minimum value of the internal friction angle of foundation soils, fill soils, or excavation slopes that would provide a safe design of the plant through soil structure interaction analyses including sliding along the base.	2.5.4	30°	Design parameter bounds Site-Specific Value.

Notes:
°F = degrees Fahrenheit
DB = dry bulb
EAB = Exclusion Area Boundary
ft = feet
hr = hour(s)
in. = inch(s)
ksf = thousand pounds per square foot
lb = pound(s)
LPZ = Low Population Zone
mi = mile(s)
mph = miles per hour
NAVD88 = North American Vertical Datum of 1988
NGVD29 = National Geodetic Vertical Datum of 1929
psf = pounds per square foot
psi = pound-force per square inch
s = second(s)

Replace Table 2.0-2 with the following:

Table 2.0-2R Site-Related Design Parameters
(Sheet 1 of 2)

Characteristic/ Parameter	PPE Value	Description	ESPA SSAR Section	CRN Site-Related Design Parameter	Comments
Structure Height	160 ft	The height from finished grade to the top of the tallest power block structure, excluding stacks and cooling towers.	3.5.1.6	<103 ft	Smaller than ESPA PPE.
Structure Foundation Embedment	138 ft	The depth from finished grade to the bottom of the basemat for the most deeply embedded power block structure.	2.4.12	<120 ft	Smaller than ESPA PPE.
Plant Megawatts Thermal	800 MWt (805 MWt including reactor coolant pump) [2420 MWt]	The maximum thermal power generated by one unit and the maximum thermal power for the site.	1.2.2	870 MWt	Smaller than ESPA PPE for site total; larger than ESPA PPE for a single unit.
Minimum Site Grade	821 ft NAVD88	Minimum finished ground elevation in the power block area.	2.4.1	814.5 ft NAVD88	Smaller than ESPA PPE.
Condenser/Heat Exchanger Design Duty	[5593 MBTU/hr]	Design value for the waste heat rejected to the circulating water system across the condensers.	-	~570 MW (1646 MBTU/hr)	Smaller than ESPA PPE.
Gaseous Releases					
Source Term (Accident)	Refer to ESPA SSAR Table 2.0-3	Bounding design basis accident atmospheric release by post-accident interval.	15.2	Table 2.0-3R	ESPA PPE is bounding.
Source Term (Normal)	Refer to ESPA SSAR Table 2.0-4	Annual activity, by radionuclide, contained in routine plant airborne effluent streams.	11.3.3	Table 2.0-4R	ESPA PPE is bounding.
Release Point Elevation					
Accident	Ground level	The elevation above finished grade of the release point for releases due to an accident.	2.3.4	Ground level	Same as ESPA PPE.
Normal	Ground level	The elevation above finished grade of the release point for normal effluent releases.	2.3.5	Ground level release is assumed for normal release	The CRN-1 source term is bounded by the ESPA source term.

Table 2.0-2R Site-Related Design Parameters
(Sheet 2 of 2)

Characteristic/ Parameter	PPE Value	Description	ESPA SSAR Section	CRN Site-Related Design Parameter	Comments
Liquid Releases					
Source Term (Accident)	Refer to ESPA SSAR Table 2.0-5	The assumed activity, by radionuclide, contained in accidental liquid radwaste release.	2.4.13	Table 2.0-5R	ESPA PPE is bounding.
Source Term (Normal)	Refer to ESPA SSAR Table 2.0-6	Annual activity, by radionuclide, contained in routine plant liquid effluent streams.	11.2.3	Table 2.0-6R	ESPA PPE is bounding.

Notes:
ft = feet
hr = hour(s)
MBTU = millions British thermal units
MW = megawatt(s)
MWt = megawatt thermal
NAVD88 = North American Vertical Datum of 1988

(a)**Bold** text indicates that CRN-1 value exceeds PPE value. The specific radionuclides that exceed ESP PPE are considered to be minor dose contributors with respect to the considered dominant dose contributing radionuclides. The dominant dose contributing radionuclides (e.g., I-131, Cs-137, and H-3) exceed CRN-1 by many orders of magnitude.

Table 2.0-4R CRN-1 Projected Annual Normal Gaseous Radioactive Release (Ci/yr)
(Sheet 3 of 3)

Radionuclide	ESPA PPE Total Site Release	CRN-1 Release[(a)]
Zn-65	6.86E-03	1.3E-04
Zr-95	3.00E-03	5.1E-05
Total (without H-3)	6.12E+03	6.4E+02
H-3	1.01E+03	2.6E+01
Total Gaseous Radionuclide Release Activity	7.13E+03	6.6E+02

(a) **Bold** text indicates that CRN-1 value exceeds PPE value.

(b) BWRX-300 short-lived radionuclide exceedances (Kr-89 and Xe-137) are shown to be acceptable because of significant decay during atmospheric transport between the source and offsite receptors.

(c) Based on population dose results presented in ESPA SSAR Table 11.2-9, higher BWRX-300 C-14 radionuclide releases are offset by lower H-3 emissions.

(d) Based on Gaseous Radioactive Effluent Concentrations at the Site Exclusion Area Boundary presented in ESPA SSAR Table 11.3-3 for noble gases, higher BWRX-300 Kr-83m, Xe-135m, and Xe-138 radionuclide releases are offset by lower Ar-41 noble gas emission.

(e) Based on Gaseous Radioactive Effluent Concentrations at the Site Exclusion Area Boundary presented in ESPA SSAR Table 11.3-3, higher BWRX-300 Rh-103m releases are offset by lower Co-60 particulate radionuclide release source term.

(f) Rh-106 increases are negligible contributors to dose because of decay during atmospheric transport to the site boundary

(a)**Bold** text indicates that BWRX-300 value exceeds PPE value. The dominant dose contributing radionuclides (e.g., I-131, Cs-137, and H-3) calculated for CRN-1 are exceeded by many orders of magnitude by the corresponding ESPA PPE values.

2.1 Geography and Demography

Section 2.1 of the referenced ESPA SSAR is incorporated by reference with the following supplements.

2.1.1 Site Location and Description

2.1.1.1 Specification of Location

Replace Reference 2.1-10 with Reference 2.1-13

Replace Reference 2.1-12 with Reference 2.1-14

Replace Reference 2.1-16 with Reference 2.1-18

Replace the fourth paragraph with the following:

The CRN Site is approximately 935 acres (ac) and is located on a peninsula formed by a meander in the Clinch River arm of the Watts Bar Reservoir. The approximately 1200-ac CRN Property is bounded on the east, south, and west by the Clinch River arm of the Watts Bar Reservoir, and on the north by the U.S. Department of Energy's Oak Ridge Reservation and Wildlife Management Area. The site is situated on the historical Clinch River Breeder Reactor Project (CRBRP) Site. At the time of the project's cancellation in 1983, preliminary site work was essentially completed for the CRBRP, including all necessary sediment ponds, construction shops, concrete batch plants, the nuclear island excavation, and a foundation for a ringer crane. Approximately three million cubic yards of earth and rock were removed during this excavation. Upon project termination, the main site area of approximately 182 ac was remediated in accordance with the Site Remediation Plan. This included partial backfilling of the nuclear island excavation. The finished elevation for the remediated nuclear island excavation area was set at approximately 814.5 ft.

2.1.2 Exclusion Area Authority and Control

2.1.2.1 Site Area Map

Replace Reference 2.1-13 with Reference 2.1-15

2.1.2.2 Control of Activities Unrelated to Plant Operation

Replace Reference 2.1-13 with Reference 2.1-15

Replace Reference 2.14 with Reference 2.1-16

Replace Reference 2.15 with Reference 2.1-17

2.1.3 Population Distribution

*This section is replaced in its entirety with the following. TVA has updated the 2010 census data in the ESPA with data collected in 2020 (*Reference 2.1-9*). While the numbers have changed slightly, the trends remain the same.*

Population distributions calculated for the Clinch River Nuclear (CRN) Site were derived by an approach that accounts for multiple units at the CRN Site. This approach results in “analytical Exclusion Area Boundaries (EABs)” encompassed by an ellipse with a short axis of 0.326 mi (0.524 meters) from the site center point and a long axis of 0.535 mi (0.864 meters) from the center point. To maintain consistency with the ESPA ER site center point, a 0.535-mi radius was used to establish a buffer for the demographic components of the CPA ER.

Thus, population distributions calculated for the Clinch River Nuclear (CRN) Site were calculated at 0.535 mi (0.864 meters) from the site center point. Thus, distance measurements in relation to the CRN Site in this report are made from the buffered site center point.

The population surrounding the site, up to a 50-mi (80-kilometers [km]) radius, was estimated based upon the most recent 2020 U.S. Census Bureau (USCB) decennial census data. The population estimates were distributed into fifteen concentric bands at 0–0.3 mi (0.5 km), 0.3–1 mi (1.6 km), 1–2 mi (3.2 km), 2–3 mi (4.83 km), 3–4 mi (6.44 km), 4–5 mi (8.05 km), 5–6 mi (9.66 km), 6–7 mi (11.3 km), 7–8 mi (12.9 km), 8–9 mi (14.5 km), 9–10 mi (16.1 km), 10–20 mi (32.2 km), 20–30 mi (48.3 km), 30–40 mi (64.4 km), and 40–50 mi (80.5 km) from the buffered site center point. These bands are subdivided into 16 directional sectors, each centered on one of the 16 compass directions and consisting of 22.5 degrees. Population sectors out to 10 mi (16 km) are shown in Figure 2.1-6R, and population sectors out to 50 mi (80 km) are shown in Figure 2.1-7R.

Population projections were obtained from the University of Tennessee’s Boyd Center for Business and Economic Research, the University of Louisville’s Kentucky State Data Center, and the North Carolina Office of State Budget & Management. Projections from each of these sources were available by county; projections for counties in Tennessee extended through 2070 while the population projections for counties in Kentucky and North Carolina were available through 2050. The counties that were used for the population projections are listed in Figure 2.2-1R. The percentage change in the population of each county in the 50-mi (80 km) radius from 2020 to 2025 was calculated, and the resultant growth rate was used in conjunction with the 2020 census data to produce a growth ratio. Calculations of population growth rates were continued in 5-year increments through the end of the available dataset for each jurisdiction (2050 or 2070). For counties located in Kentucky and North Carolina, the projected growth rate at the end of the available dataset (from 2045 to 2050) was used to calculate subsequent projections through 2070. For counties lacking a positive projected growth rate for the entirety of the licensing period, the population of that county was conservatively held constant (zero percent increase) for the remaining projections through 2070.

Census population counts (provided at the block level) were sorted into each of the directional sectors. Because census block boundaries may be split between sector boundaries, the

proportion of each block within a sector was determined. Accordingly, the percentage of the census block population allocated to each sector corresponded to the percentage of the census block land area in the sector. Finally, the population of each sector was calculated by summing the population of each block or portion of a block located within that sector. The years selected for the projection period represent the 2020 census, and every 10-years thereafter until the anticipated end of normal plant license period (2070).

2.1.3.1 Population Within 10 Miles

Permanent population is projected every 10-years thereafter 2020 until the anticipated end of normal plant license period (2070). The projected permanent and transient population for each sector out to 10 mi (16 km), for the years 2030, 2040, 2050, 2060, and 2070 is shown on Table 2.1-2R. Population for all sectors in the 10-mi (16-km) radius for each projected year is shown in the “Totals” field of Table 2.1-2R. The project population estimated for the year 2020 for the 10-mi (16-km) radius of the buffered site center point is shown in Figure 2.1-6R.

A notable special population source within 10 mi (16 km) of the site is the Oak Ridge National Laboratory (ORNL). ORNL employs a total of 5,772 staff and the Y-12 National Security Complex which employs 7,241 staff (Reference 2.1-1). While these employees were counted by the USCB at their residences, a portion of this workforce, based on commuter data trends, were transient within the 10-mi radius.

2.1.3.2 Population Between 10 and 50 Miles

Figure 2.1-7R shows the estimated regional permanent population for the year 2020 within 50 mi (80 km) of the buffered site center point. The region between 10 and 50 mi (16 and 80 km) includes all or part of the counties listed in Figure 2.2-1R. The distances defining the sectors are 10 mi (16 km), 20 mi (40 km), 30 mi (48 km), 40 mi (64 km), and 50 mi (80 km).

Knoxville is the largest city within 50 mi, with a 2020 population of 599,356. Smaller cities within the region include Sevierville (23,305), Athens (15,935), Crossville (16,377), La Follette (19,504), Cleveland (71,855), Morristown (60,492), Oneida (4,482), Strawberry Plains (2,739), Dayton (19,937), Fairfield Glade (7,783), Sweetwater (5,374), Harriman-Kingston-Rockwood (21,814), Madisonville (5056), Etowah (3870) and Norris (3,537) (Reference 2.1-10). Many other smaller towns and cities are distributed within the region.

The projected permanent population for each sector in the 10-50 mi (16-80 km) region for the years 2030, 2040, 2050, 2060, and 2070 is shown Table 2.1-3R. Permanent population is projected every 10-years thereafter until the anticipated end of normal plant license period (2070). The total number of people in the 10-50 mi (16-80 km) region for each projected year is shown in the “Totals” field of Table 2.1-3R.

2.1.3.3 Transient Population

Per Regulatory Guide (RG) 4.7, transients are defined as people (other than those just passing through the area) who work, reside part time, or engage in recreational activities but are not permanent residents of the area (Reference 2.1-7). Transient populations are additionally

defined by NUREG-0800, as workers, occupants of schools, hospitals, recreational facilities, and others who do not permanently reside in the area (Reference 2.1-6).

Analysis of transient populations within the 10-mi (16 km) radius included an assessment of major population generators such as employers, tourists and recreational areas, educational facilities, hospitals, national and state parks, and recreation areas. Population attending local public venues are not counted as transients as this is likely to result in over-estimates of transient populations due to the high contribution of attendance at these venues by permanent residents within the 0- to 10-mi (0- to 16-km) area.

Though relatively rural in nature, the region surrounding the site has numerous facilities and recreation areas that contribute to the transient population. Transient data was gathered from the East Tennessee Economic Development Agency, National Center for Education Statistics, Tennessee Department of Human Services, Tennessee Department of Health, Early Site Permit Application (ESPA) Demographic Calculation (Reference 2.1-1), and Google Earth search within the region. This method for collecting transient data provided a more accurate assessment of people visiting the area and a much more precise location of transient contributors. The identified transient facilities that contribute to the transient population in the 0- to 10-mi region are shown in Table 2.1-4R.

RG 1.70 requires that seasonal and daily variations in population and population distribution resulting from land uses such as recreational or industrial should be generally described within the 10-mi and 50-mi (16-km and 80-km) radius (Reference 2.1-5). There are several national and state parks that contribute to the regional transient population (10-50 mi [16-80 km] radius), these parks and visitor counts are detailed in Table 2.1-6R.

2.1.3.3.1 Transient Population Within 10 Miles (16 km)

Table 2.1-4R lists the daily visitors for all transient facilities identified within a 10-mi (16 km) area of the buffered site center point. There were 84 individual transient facilities identified within 10 mi (16 km) of the site that contribute approximately 12,700 daily visitors to the transient population (Table 2.1-5R). The largest transient facilities within 10 mi (16 km) of the site include, the Y-12 National Security Complex, an employer contributed 3,548 transients, Oak Ridge National Laboratory, an employer, contributed 2,831 transients, and Mayor Bob Leonard Park, at full capacity contributed 570 transients (Table 2.1-5R).

2.1.3.3.2 Total Permanent and Transient Populations within 10 Miles (16 km)

Table 2.1-2R summarizes the total permanent and transient population by sector and year of interest within the 0- to 10-mi (0- to 16- km) radius. The estimated permanent and transient population for 2020 in the 10-mi (16 km) radius was approximately 98,127 (Table 2.1-2R). Using calculated county growth rates, the estimated total population for 2070 is 119,055 (Table 2.1-2R).

2.1.3.3.3 Transient Population Between 10-50 Miles (16-80 km)

Transient populations were identified in the 10- to 50-mi (16- to 80- km) radius, in accordance with RG definitions of transient and included a review of employment in major economic centers

and recreation areas. The Knoxville, Tennessee metro area falls within 10 and 50 mi of the CRN Site. The Knoxville, Tennessee economic center includes the counties of Morgan, Roane, Loudon, Blount, Knox, Anderson, Campbell, Union, and Grainger, all of which fall within the 50 mi (80 km) radius. Recreational contributors to the regional total transient population include state and national parks. Table 2.1-6R lists the state and national parks located within the region. Annual visitation reflects data obtained from 2017-2021 depending on the park. The Great Smoky Mountains National Park had the largest transient population, with a recorded annual visitor count of 14,161,548 persons (Reference 2.1-4). There are 18 Tennessee state parks, national parks, and national forests within the 50-mi (80 km) region. The state park with the largest daily visitor estimate is the Hiwassee Ocoee State Park with approximately 1,714 daily visitors. The remaining state parks have daily visitation that ranges from 556 to 54 persons. The remaining national parks within the region are the Big South Fork National River and Recreation Area, Obed Wild and Scenic River, and Manhattan Project National Historic Park. The national forests within the region are Cherokee National Forest, Daniel Boone National Forest, and Nantahala-Pisgah National Forest (Reference 2.1-4). The peak daily visitor estimates for state and national parks within the region that contribute to the total transient population are listed in Table 2.1-6R.

2.1.3.4 Low-Population Zone

For the CRN Site, the low-population zone (LPZ) is defined as a 1 mi (1.6 km) radius from the site center point. Figure 2.1-8R illustrates the LPZ and total permanent and transient population by sector.

According to the USCB 2020 data, there are 112 people living within the LPZ (Table 2.1-8). The distribution of permanent and transient populations within the LPZ in the 16 cardinal directions is provided in Table 2.1-8. There are no transient facilities within the LPZ, however transient facilities within 5 mi (8 km) of the site center point are identified on Figure 2.1-9R (Reference 2.1-8 and Reference 2.1-3).

2.1.3.5 Population Center

Population centers, as defined by 10 Code of Federal Regulations (CFR) 100.3, are densely populated clusters containing more than 25,000 people. To identify population centers within the site region, the USCB census-delineated urban areas were used (Reference 2.1-11). Rather than being based on political boundaries, census-defined urban areas are based largely on population density (Reference 2.1-11). Table 2.1-8 details and Figure 2.1-10 illustrates the urban areas and population centers identified within the 50-mi (80-km) radius. Of the urban areas located within the region, only three met the requirements to be classified as population centers in 2020: Knoxville (599,356 persons), Cleveland (71,855 persons), and Morristown (60,492 persons) Tennessee. The Knoxville urban area is a combination of several smaller cities, including Alcoa, Clinton, Coalfield, Eagleton Village, Farragut, Friendsville, Halls, John Sevier, Karns, Knoxville, Lenoir City, Loudon, Louisville, Maryville, Mascot, Oak Ridge, Oliver Springs, Powell, Rockford, Sevierville, Seymour, Tellico Village, and Wildwood, Tennessee. The Cleveland urban area is a combination of seven smaller cities. The Morristown urban area is a combination of five smaller cities (Reference 2.1-11). The closest urban area to the CRN Site is the

Harriman-Kingston-Rockwood, Tennessee area, located approximately 3.4 mi (5.5 km) west of the CRN Site. RG 4.7 stipulates that the nearest population center must be at least one-and-one-third times the distance from the reactor to the LPZ (Reference 2.1-7). The distance between the site center point to the nearest boundaries of the closest population center are greater than one and one-third times the distance from the site center point to the boundary of the LPZ.

Using the county population projection ratios, the populations of one additional urban area is anticipated to meet the population center criteria by 2070: Sevierville, Tennessee. At the anticipated end of normal plant license period, Knoxville remains the largest population center to the site with an estimated 2070 population of 843,955. However, Harriman—Kingston—Rockwood remains the closest urban area to the site.

The City of Oak Ridge, with a 2020 population of 31,402, is the closest city to the CRN Site that exceeds 25,000 people (Reference 2.1-9). The CRN Site is located within the southern extent of the City of Oak Ridge, with the city's territory primarily extending to the northeast of the CRN Site. The densely populated portions of the City of Oak Ridge are located in these northeast portions. Therefore, densely populated portions of the City of Oak Ridge are located beyond the distance required by RG 4.7. This is further supported by the U.S. Census Bureau, which has delineated the densely populated portions of the City of Oak Ridge as part of the greater Knoxville urban area (Reference 2.1-11).

The transient population is not considered in these calculations because 10 CFR 100.3 defines a population center as "the distance from the reactor to the nearest boundary of a densely populated center containing more than about 25,000 residents." Transient populations by nature are not considered to be part of the resident population.

2.1.3.6 Population Density

RG 4.7 recommends that at the time of the projected initial site approval and within about 5 years thereafter, the population density, including weighted transient population, averaged over any radial distance out to 20 mi, should not exceed 500 persons per square mile (Reference 2.1-7). Additional guidance from RG 1.70 states that the cumulative resident population out to 30 mi should not exceed 500 people per square mile for the estimated initial year of operation (2030) or 1,000 people per square mile at the anticipated end of normal plant license period (2070) (Reference 2.1-5). For the purpose of evaluating projected population densities per the above mentioned RGs, population densities were calculated to a distance of 30-mi (48 km). Transient population within the 0- to 30-mi (0- to 48-km) area were weighted according to the fraction of the time the transient populations were expected to be in the area. The weighted transient population was projected out to 2070 and combined with the residential population resulting in a cumulative resident and weighted transient population. Population densities were derived by taking the cumulative total projected population at a distance divided by the area at that distance for the estimated year of initial operation (2030), five years after (2035), and the anticipated end of normal plant license period (2070). The 2030, 2035, and 2070 cumulative total projected population at a distance of 30-mi is approximately 798,304, 822,782, and 1,000,456, respectively.

The relationship between cumulative population totals and USNRC siting criteria is illustrated in Figure 2.1-11. This blue line on the figure represents the number of people within that distance equivalent to a population density of either 500 or 1000 per mi^2. Cumulative projected populations at those distances are represented by the green line. By comparing the curves, it is evident that cumulative projected populations within 30-mi (80 km) of the CRN Site does not exceed guidance criteria.

2.2 Nearby Industrial, Transportation and Military Facilities

Section 2.2 of the referenced ESPA SSAR is incorporated by reference with the following supplements.

2.2.1 Locations and Routes

Delete the first bullet of the first paragraph of ESPA SSAR Section 2.2.1.

Replace the second paragraph to the end of ESPA SSAR Section 2.2.1 with the following:

An investigation of the identified potential external hazard facilities and operations (Figure 2.2-1R) within the 5-mi vicinity of the CRN Site identified the following significant industrial facilities for assessment (Reference 2.2-11).

- Diversified Scientific Services
- Duracap Asphalt Paving
- East Tennessee Technology Park
- Energy Solutions Services – Bear Creek Facility
- Harrison Construction – Gallaher Concrete Plant
- Knoxville PDC - Volkswagen Group of America
- NAC Philotechnics – Horizon Center
- Oak Ridge National Laboratory – Battelle
- Oak Ridge National Laboratory – UCOR
- TVA Melton Hill Hydro Plant
- Weigel's #58

An evaluation of the identified major transportation routes within the 5-mi vicinity of the CRN Site (Figure 2.2-2) identified one navigable waterway, one major highway, four major roads, one minor rail line, and two natural gas pipelines for assessment (Reference 2.2-1, Reference 2.2-2 and Reference 2.2-3):

- Clinch River arm of Watts Bar Reservoir (Reference 2.2-20 through Reference 2.2-22 and Figure 2.2-2)
- Interstate 40 (I-40) (Reference 2.2-27 and Figure 2.2-2)
- Tennessee State Highway 1 (TN 1)/US11-70, and Tennessee State Highways 58 (TN 58), 95 (TN 95), and 327 (TN 327) (Reference 2.2-27)
- Heritage Railroad Corporation Railway (Reference 2.2-1 and Reference 2.2-3)
- Two active natural gas transmission pipelines: East Tennessee Natural Gas Pipeline 1 (East) and Pipeline 2 (North) (Reference 2.2-5)

An evaluation of nearby industrial facilities and transportation routes beyond the 5-mi vicinity of the CRN Site was undertaken. In going beyond 10 mi of the CRN Site, particular attention was

paid to identifying whether any facilities contain highly toxic, highly volatile chemicals with Risk Management Program (RMP) calculated endpoint distances of at least 25 mi (Reference 2.2-6). The following industrial facilities located beyond the 5-mi vicinity of the site were identified for assessment (Reference 2.2-11 and Reference 2.2-28):

- Diversified Scientific Services
- Duracap Asphalt Paving
- East Tennessee Technology Park
- Energy Solutions Services – Bear Creek Facility
- Harrison Construction – Gallaher Concrete Plant
- Knoxville PDC – Volkswagen Group of America
- NAC Philotechnics – Horizon Center
- Oak Ridge National Laboratory – Battelle
- Oak Ridge National Laboratory – UCOR
- TVA Melton Hill Hydro Plant
- Weigel's #58

The evaluation of transport routes beyond the 5-mi vicinity of the CRN Site identified both rail transport and roads. Rail transport within 5 to 10 mi of the site includes two major and one minor rail line. At closest approach, the two major rail lines operated by Norfolk Southern are 7 mi or more from the CRN Site. In addition to being farther than 5 mi, these rail lines are within complex intervening terrain and therefore accident scenarios on those lines are not evaluated further. The minor rail line, operated by EnergySolutions Heritage Railroad Corporation, is an extension of the EnergySolutions Heritage Railroad Corporation Railway identified within the 5-mi vicinity of the CRN Site. This rail spur is used by Carbon Rivers to transport materials for recycling wind turbine blades (Reference 2.2-25). Wind turbine blades do not pose a threat to the CRN site due to their physical properties. Solids have a vapor pressure sufficiently low such that the formation of a vapor cloud is not likely. That is, the air dispersion hazard of the material is not a likely exposure route. Nor is the solid material considered explosive. Therefore, this railway is not considered further in this evaluation.

Roads identified beyond the 5-mi vicinity of the CRN Site included I-75 and other major roads. I-75 and other major roads located between 5 and 10 mi of the CRN Site are not considered further given that I-40 was identified within the 5-mi vicinity of the site, where plausible chemicals may be transported, and would, therefore, bound an analysis of roads located farther away.

There are no identified roads, railways or navigable waterways at distances greater than 10 mi that are significant potential hazards.

In summary, the evaluation identified several industrial facilities, one major highway, four major roads, and two natural gas pipelines that are significant enough to be considered for further review (Figure 2.2-1R and Figure 2.2-2). These include:

Industrial Facilities

- Facilities are identified in Table 2.2-1R

Transport Routes

- Clinch River arm of Watts Bar Reservoir
- I-40
- TN 1/US11-70, and TN 58, TN 95, and TN 327
- Energy Solutions Railway
- East Tennessee Natural Gas Pipeline 1 (East) and Pipeline 2 (North)

Airports and Airways

Figure 2.2-3R illustrates the following identified airports and airway routes within 10 mi of the CRN Site (Reference 2.2-7 and Reference 2.2-8):

- Big T
- Wolf Creek
- Cox Farm
- Will A Hildreth Farm
- Meadowlake
- Oak Ridge Airport (Under Development)
- Federal Airways V16, J46 and Q65

The Oliver Springs and Fergusons Flying Circus airports are within 10 to 15 mi of the CRN Site (Reference 2.2-7).

2.2.2 Descriptions

Replace ESPA SSAR Section 2.2.2 with the following:

Descriptions of the industrial, transportation, and military facilities located in the vicinity of the CRN Site and identified in Section 2.2.1 are provided in the subsequent subsections in accordance with SRP 2.2.1-2.2.2

2.2.2.1 Descriptions of Facilities

Replace ESPA SSAR Section 2.2.2.1 with the following:

The facilities identified for further review are listed in Table 2.2-1R. Table 2.2-1R provides a concise description of each facility, including its primary function and major products.

2.2.2.2 Description of Products and Materials

Replace ESPA SSAR Section 2.2.2.2 with the following:

A more detailed description of offsite chemicals associated with each of the above facilities is provided in the following subsections. This description includes information about the products and materials regularly manufactured, stored, used or transported in the site vicinity. In keeping with the guidance of RG 1.78, chemicals stored or situated at distances greater than the 5-mi vicinity of the proposed CRN Site are not considered unless they are determined to potentially have a significant impact on the proposed CRN Site. The U.S. Environmental Protection Agency's (EPA's) Envirofacts/Enviromapper database was queried for facilities and sent to the Military Department of Tennessee in a request for the Superfund Amendments and Reauthorization Act (SARA) Title III, Tier II reports for the queried facilities (References 2.2-10 and 2.2-11).

In addition to the request submitted to the Military Department of Tennessee, the RMP database was queried to obtain reports for facilities within a 25-mile radius of the CRN site (Reference 2.2-28). The facilities identified herein were determined to have a possible significant impact on the CRN Site; therefore, further analysis of facilities other than these is not required.

2.2.2.2.2 Industrial Facilities

Replace the first paragraph of ESPA SSAR Section 2.2.2.2.2 with the following:

ORNL (Battelle)

ORNL is located in Oak Ridge, TN, approximately 4.3 mi northeast of the CRN Site power block area. ORNL conducts research and development relating to national energy and security issues and employs approximately 6000 employees (Reference 2.2-17).

Delete paragraphs 2 and 3 from ESPA SSAR Section 2.2.2.2.2.

TVA Kingston Fossil Plant

Replace first sentence of the 4th paragraph of ESPA SSAR Section 2.2.2.2.2 with the following:

TVA – Kingston Fossil Plant is located in Kingston, TN, approximately 7.7 mi west of the CRN Site power block area.

Delete paragraphs 5 through 7 from ESPA SSAR Section 2.2.2.2.2.

Oak Ridge Water Treatment Plant

Replace the first sentence of the 8th paragraph of ESPA SSAR Section 2.2.2.2.2 with the following:

The Oak Ridge WTP is located in Oak Ridge, TN, approximately 10 mi northeast of the CRN Site power block area.

Delete paragraphs 9 through 15 of ESPA SSAR Section 2.2.2.2.2

Delete paragraphs 17 through 19 of ESPA SSAR Section 2.2.2.2.2

Insert the following after the last paragraph of ESPA SSAR Section 2.2.2.2.2:

A. E. Staley Manufacturing / Tate & Lyle Manufacturing

A.E. Staley Manufacturing and Tate & Lyle Manufacturing are the same company and operate a facility located in Loudon, TN, approximately 11 miles south of the CRN site. This facility develops ingredients for food products and beverages (Reference 2.2-54). The facility uses sulfur dioxide as part of the processes.

City of Maryville Wastewater Treatment Plant

The City of Maryville Wastewater Treatment Plant (Reference 2.2-55) is located approximately 24 miles east of the CRN site. The facility uses chlorine as a disinfectant.

City of Oak Ridge Municipal Pool

The City of Oak Ridge Municipal Pool is located approximately 10.8 miles northeast of the CRN site. The municipal pool is provided for recreational purposes (Reference 2.2-56). The pool uses chlorine as a disinfectant.

Custom Foods of America

Custom Foods of America is located approximately 23.6 miles east of the CRN site. This facility develops food products for restaurants and convenience stores (Reference 2.2-57). The facility uses anhydrous ammonia as part of the processes.

Diversified Scientific Services

Diversified Scientific Services is located approximately 3.4 miles west of the CRN site. This facility provides radioactive waste treatment services (Reference 2.2-58). The facility uses sodium hydroxide as part of the processes.

Duracap Asphalt Paving

Duracap Asphalt Paving is located approximately 2.3 miles southeast of the CRN site. This facility provides construction materials for asphalt paving, grading, drainage and site utilities (Reference 2.2-59).

East Tennessee Mechanical Contractors Water Treatment Plant

East Tennessee Mechanical Contractors WTP (Reference 2.2-60) is located approximately 10.5 miles northeast of the CRN site. The company treats water in support of the work processes. The facility uses chlorine as a disinfectant as part of water treatment.

East Tennessee Technology Park

East Tennessee Technology Park (Reference 2.2-61 and Reference 2.2-62) is currently undergoing a clean-up / remediation effort. The technology park is located approximately 3 miles north of the CRN site. The facility uses gasoline during the clean-up / remediation efforts.

Energy Solutions Services – Bear Creek Facility

The Energy Solutions Services – Bear Creek Facility is located on Bear Creek Road, approximately 1.6 miles north of the CRN site. The facility processes radioactive waste (Reference 2.2-63). The facility uses nitric acid and propane as part of the processes.

First Utility District of Knox County Water Treatment and Wastewater Treatment Facilities

The First Utility District of Knox County operates a water treatment facility (Reference 2.2-64) and a wastewater treatment facility (Reference 2.2-65). The water treatment facility is located approximately 14.2 miles east of the CRN site. The wastewater treatment facility is located approximately 13.4 miles east of the CRN site. Both facilities use chlorine as part of the treatment processes.

Food Lion – Delhaize Distribution Center

The Food Lion – Delhaize Distribution Center is located approximately 20 miles northeast of the CRN site. The distribution center provides food to the grocery stores in the vicinity (Reference 2.2-66). The distribution center uses anhydrous ammonia.

Fourth Creek Wastewater Treatment Plant

Knoxville has two wastewater treatment plants (Reference 2.2-67). The Fourth Creek wastewater treatment plant is located approximately 22 miles east of the CRN site. The facility uses chlorine as part of the treatment process.

Harrison Construction – Gallaher Concrete Plant

Harrison Construction operates the Gallaher Concrete Plant (Reference 2.2-68). The Gallaher Concrete Plant is located approximately 3 miles west of the CRN site. This facility provides construction materials, including aggregate and ready mix concrete.

Knoxville PDC - Volkswagen Group of America

Volkswagen Group of America is a distribution service (Reference 2.2-82). The facility is located approximately 1 mile southeast of the CRN site. Electric cars at the facility contain lead and sulfuric acid.

Linde Inc.

Linde Inc. is a local gas and equipment supplier (Reference 2.2-69). The facility is located approximately 11 miles south of the CRN site. Linde Inc. stores anhydrous ammonia and carbon dioxide.

NAC Philotechnics – Horizon Center

NAC Philotechnics operates the Horizon Center. The Horizon Center is located approximately 4.9 miles north of the CRN site. This facility provides radioactive and mixed waste treatment services (Reference 2.2-70).

ORNL - UCOR

UCOR is involved with deactivation and demolition work at ORNL (Reference 2.2-71). The facility is located approximately 4.9 miles north of the CRN site. Nitric acid is used as part of the processes.

Primary Products Ingredients Americas, LLC

Primary Products Ingredients is located in Loudon, TN, approximately 11 miles south of the CRN site. This facility develops ingredients for food products and beverages (Reference 2.2-72). The facility uses anhydrous ammonia as part of the processes.

Processed Food Corporation

Processed Food Corporation is located approximately 23.6 miles east of the CRN site. The facility develops food products for restaurants and convenience stores (Reference 2.2-73). The facility uses anhydrous ammonia as part of the processes.

Tellico Area Service System Water Treatment Plant

The Tellico Area Service System WTP (Reference 2.2-74) is located approximately 21.8 miles south of the CRN site. The facility uses chlorine as part of the treatment process.

Tennessee Valley Authority - Melton Hill Hydro Plant

TVA operates the Melton Hill Hydro Plant (Reference 2.2-75). The Melton Hill Hydro Plant is located approximately 4.7 miles east-southeast of the CRN site. The facility uses chlorine as part of the treatment process.

U.S. Foodservice - Knoxville

U.S. Foodservice provides food distribution to restaurants (Reference 2.2-76). The facility is located approximately 23.3 miles southeast of the CRN site. The facility uses anhydrous ammonia.

Weigel's #58

Weigel's is a convenience store that dispenses fuel and other commodities (Reference 2.2-77). Store #58 is located approximately 3.7 miles west of the CRN site. Weigel's stores gasoline, diesel and propane.

West Knox Utility District

West Knox Utility District operates a water treatment facility (Reference 2.2-78) and a wastewater treatment facility (Reference 2.2-79). The water treatment facility is located approximately 9.1 miles northeast of the CRN site. The wastewater treatment facility is located approximately 14.4 miles northeast of the CRN site. Both facilities use chlorine as part of the treatment processes.

Yale Security Inc.

Yale Security manufacturers commercial locks and hardware at a facility in Lenoir City (Reference 2.2-80), located approximately 9.5 miles southeast of the CRN site. The facility uses chlorine as part of the manufacturing processes.

As provided in RG 1.78, chemicals stored or situated at distances greater than 5 mi from CRN do not need to be considered because if a release occurs at such a distance, atmospheric dispersion will dilute and disperse the incoming plume to such a degree that either toxic limits will never be reached or there would be sufficient time for the control room operators to take appropriate action. Although several of the facilities are located greater than 5 mi from the CRN Site, some of these were identified for further analysis because of their use of anhydrous ammonia, chlorine or sulfur dioxide. According to 40 CFR 68, anhydrous ammonia, chlorine and sulfur dioxide are highly toxic/highly volatile chemicals with greater toxic endpoints and requires an offsite consequence analysis with a worst-case release scenario for RMPs under the Clean Air Act.

The chemicals stored at these facilities identified for possible analysis are presented in Table 2.2-2R. The disposition of hazards associated with these chemicals is summarized in Table 2.2-5R and the subsequent analysis of these chemicals is addressed in Subsection 2.2.3 For facilities located more than 5 miles from the CRN Site, Table 2.2-5R only list those chemicals identified as very hazardous substances per 40 CFR 68.130; such as ammonia, chlorine and sulphur dioxide.

The transportation route used for shipping and receiving supplies at the facilities may vary, and unless a material is prohibited on a route, there are no restrictions that would prevent the driver from taking another route. The I-40 corridor is identified as the most significant and closest highway to the CRN Site. Therefore, it is conservatively assumed that the chemicals stored at

these facilities are transported along the I-40 corridor, in close proximity to the CRN Site, and are included in the evaluation of potential accidents associated with nearby transport routes.

2.2.2.3 Description of Pipelines

Insert the following after the first paragraph of ESPA SSAR Section 2.2.2.3

Subsequent to the SSAR, Spectra Energy was acquired by Enbridge Inc. and operates under this name." (Reference 2.2-5)

2.2.2.4 Description of Waterways

Replace the 2nd paragraph of ESPA SSAR Section 2.2.2.4 with the following:

Significant waterborne transport in the CRN Site vicinity is only possible on the Clinch River arm of the Watts Bar Reservoir. Annual waterborne commerce data compiled by the United States Army Corps of Engineers' Waterborne Commerce Statistics Center, for the period of 2015 through 2021, indicate that there was inconsequential shipping on the river, that is there was no transport of hazardous materials (e.g., chemicals and related products, petroleum, ordinance, etc.) that could pose a threat to operations at the CRN Site (Reference 2.2-20 through Reference 2.2-22). As a result of this finding, waterborne shipping did not warrant further consideration in determining bounding accident scenarios involving transport of hazardous materials in the CRN Site vicinity.

2.2.2.5 Description of Highways

Replace the 3rd sentence of the first paragraph of ESPA SSAR Section 2.2.2.5 with the following:

According to the Tennessee Department of Transportation (TDOT) Traffic Count Database System (TCDS) the average daily traffic for I-40 near the CRN Site was 52,212 vehicles in 2022. (Reference 2.2-2).

Replace the 3rd sentence of the second paragraph of ESPA SSAR Section 2.2.2.5 with the following:

Average daily traffic data for TN 58 and TN 95 was obtained from the TDOT TCDS (Reference 2.2-2). For 2022, the average daily traffic reported for TN 58 was 10,812 vehicles. For 2022, the average daily traffic for TN 95 was 6382 vehicles.

Replace the 4th sentence of the 2nd paragraph of ESPA SSAR Section 2.2.2.5 with the following:

While several industrial facilities are located at the East Tennessee Technology Park (ETTP) off Bear Creek Road, as detailed in Section 2.2.2.2, a search of the SARA Title III, Tier II reports and EPA's Envirofacts/Enviromapper database revealed that one facility stores hazardous materials that could potentially impact the CRN Site (i.e., Energy Solutions Services Bear Creek Facility)

(Reference 2.2-11). Bear Creek Valley is about 1.5 mi from the CRN Property on the side of Chestnut Ridge that bounds the property to the north (Reference 2.2-1).

Replace the 4th sentence of the 4th paragraph of ESPA SSAR Section 2.2.2.5 with the following:

Information obtained regarding offsite facilities took into account SRP 2.2.1-2.2.2 guidance to consider all identified facilities and activities within 5 mi of the nuclear plant and include facilities and activities at greater distances depending on their significance.

2.2.2.6 Description of Railroads

Replace from the 3rd sentence to the end of the 2nd paragraph in ESPA SSAR Section 2.2.2.6 with the following:

Materials transported on this rail line consist of shipments of wind turbine blades (Reference 2.2-25) which do not pose a threat to the CRN site due to their physical properties. As presented in Section 2.2.2.1, these materials do not pose a significant threat to the site due to the physical properties of the materials; therefore, accidents from the transport of hazardous materials in the vicinity of the CRN Site by rail are not considered further.

2.2.2.7 Description of Airports, Aircraft and Airway Hazards

Section 2.2.2.7 is reformatted to add separate sub-sections for the different types of aircraft and airway hazard.

Replace ESPA SSAR Section 2.2.2.7 with the following:

NUREG-0800 establishes that the risks as the result of aircraft hazards should be sufficiently low, in that each requires that aircraft accidents that could lead to radiological consequences in excess of the exposure guidelines of 10 CFR 50.34(a)(1) with a probability of occurrence greater than an order of magnitude of 10^{-7} per year should be considered in the design of the plant.

Further, SRP 3.5.1.6 provides that 10 CFR 100.20, 10 CFR 100.21, and 10 CFR 52.17 requirements are met if the probability of aircraft accidents resulting in radiological consequences greater than the 10 CFR 100 exposure guidelines is less than an order of magnitude of 10^{-7} per year. Additionally, these guidelines provide that the probability is considered to be less than an order of magnitude of 10^{-7} per year by inspection if the distances from the plant meet all of the criteria listed below:

1. The plant-to-airport distance, D, is between 5 and 10 statute miles, and the projected annual number of operations is less than 500 D2, or the plant-to-airport distance, D, is greater than 10 statute miles, and the projected annual number of operations is less than 1000 D2;

2. The plant is at least 5 statute miles from the nearest edge of military training routes, including low-level training routes, except for those associated with usage greater than 1000 flights per year, or where activities (such as practice bombing) may create an unusual stress situation;

3. The plant is at least 2 statute miles beyond the nearest edge of a Federal airway, holding pattern, or approach pattern.

Therefore, utilizing the proximity criteria presented above, a screening analysis was first performed to establish whether the probability of aircraft accidents for the proposed CRN Site is considered to be less than an order of magnitude of 10^{-7} per year by inspection.

2.2.2.7.1 Airports

Five small privately-owned airports (Big T, Wolf Creek, Cox Farm, Will A Hildreth Farm, and Meadowlake) are located between 5 and 10 statute mi of the CRN Site (Figure 2.2-3R). These airports have no Federal Aviation Administration (FAA) Terminal Area Forecast (TAF) data available due to their size and low number of operations; however, their projected number of operations, based on available data, is less than the significance factor (i.e., the allowable annual number of operations) called for by criterion 1 (Table 2.2-7R).

Two small privately-owned airports, Oliver Springs and Fergusons Flying Circus, are within 10 to 15 statute mi of the CRN Site (Figure 2.2-3R). No FAA TAF data is available due to their size and low number of operations. Based on available data, the projected number of operations for each airport is less than the significance factor (i.e., the allowable annual number of operations) by criterion 1, as specified in NUREG-0800 (Table 2.2-7R). Airports located at distances greater than 15 statute mi were also evaluated to confirm that each would meet the significance factor specified in criterion 1 (Table 2.2-7R).

The results, summarized in Table 2.2-7R, indicate that the proximity screening criterion 1 is met for each evaluated existing airport; therefore, no nearby existing airports need further evaluation.

A new Oak Ridge Airport (under development) is located approximately 2.25 miles north of the CRN site. The Oak Ridge Airport is planned for general aviation anticipated to begin operation in 2026. The projected total number of operations at year 20 is 15,860 with 29 based aircraft (Reference 2.2-50). Due to the proximity to the CRN site, the proposed Oak Ridge Airport does not meet proximity screen criterion 1.

2.2.2.7.2 Military Training Routes

The probability of aircraft accidents at the CRN Site was evaluated to determine if the CRN Site met proximity screening criterion 2, defined previously. The centerline of the closest military training route, IR2, is located approximately 19.2 mi to the WNW (Figure 2.2-3R). The Department of Defense Flight Information Publication, AP/1B, Area Planning Military Training Routes North and South America, also provides the width of each military training route segment. This publication denotes the width of IR2 as 5 nautical mi on each side of the centerline for the entire route. IR-type military training routes must be conducted on Instrument Flight Rules (IFR) flight plans regardless of weather conditions. The Department of Defense Flight Information publication also states that pilots must enter and exit the route via published entry and exit points or published alternate entry and exit points, and must have a specific air traffic control clearance prior to entering or exiting the route. Once on the route, the pilot must remain within the published route corridor (width and altitude). (Reference 2.2-33) The CRN Site is located about

19.2 statute mi from the centerline of this training route or approximately 13.4 statute mi from the edge of the training route.

The closest military operation area (MOA) is the Snowbird MOA located approximately 36 mi from the CRN Site (Figure 2.2-3R). The primary users of the Snowbird MOA were Air National Guard units, which have since been relocated or converted from fighter aircraft to other missions. Relatively high terrain for the eastern part of the country (Snowbird overlies the Smoky Mountains) and altitude allocated to accommodate civilian overflights severely limit the area's flexibility and utility for military operations (Reference 2.2-9).

Given this separation distance between the CRN Site and the nearest military training route (greater than 5 mi from the nearest edge of a military training route), along with the distance to the nearest MOA, criterion 2 is met.

2.2.2.7.3 Federal Airways

The probability of aircraft accidents at the CRN Site was also evaluated to determine if the CRN Site met proximity screening criterion 3, defined previously. There are two Federal airways, one victor (V) and one jet (J) route (V16 and J46, respectively) whose nearest edge lies within 2 statute mi of the CRN Site (Figure 2.2-3R and References 2.2-30 through 2.2-32). Thus, due to the proximity of Federal airways V16 and J46, the CRN Site does not meet proximity screening criterion 3. Federal airway Q65 is within the 10 mile radius of the CRN Site. Although it is screened out by the proximity screening criteria, it was added as a conservatism to the detailed evaluation due to its edge being within 5 miles of the CRN Site, but it does not have a large impact.

2.2.2.7.4 Aircraft Hazards

The CRN Site does not meet acceptance criteria 1 and 3. Therefore, as required by SRP 3.5.1.6, a detailed review of aircraft hazards was required to determine the accident probability rate.

As discussed, aircraft accidents that could lead to radiological consequences in excess of the exposure guidelines of 10 CFR 100 with a probability of occurrence greater than an order of magnitude of 10^{-7} per year should be considered in the design of the plant. However, a conservative calculation showing that the probability of occurrence of doses in excess of the exposure guidelines, of about an order of magnitude 10^{-6} per year, is acceptable, in accordance with SRP 2.2.3, if, it can be shown with rigorous analysis, using realistic assumptions and reasonable arguments, that the estimated probability can be shown to be lower.

NUREG-0800 gives the following equation for estimating the probability per year of an aircraft crashing into the plant from nearby airports and heli-ports.

$$P_A = \sum_{i=1}^{L} \sum_{j=1}^{M} C_j * N_{ij} * A_{eff_j} \qquad \text{Equation 2.2-1}$$

where:

P_A = probability of an aircraft crashing into the plant

M = number of different types of aircraft using the airport

L = number of flight trajectories affecting the site

C_j = probability per square mile of a crash per aircraft movement, per aircraft movement of the jth aircraft

N_{ij} = number of movements per year of the jth aircraft along the ith flight path

A_j = effective area of the plant in square mi for the jth aircraft

NUREG-0800 gives the following equation for estimating the probability per year of an aircraft crashing into the plant when Federal airways pass through the vicinity of the site:

$$P_{FA} = C \times N \times A_{eff} / W \qquad \text{Equation 2.2-2}$$

where,

P_{FA} = the probability of an aircraft crashing into the plant

C = the in-flight crash rate per mi for aircraft using the airway

N = the number of flights per year along the airway

A_{eff} = the effective area of the plant in square mi

W = the width of the airway (plus twice the distance from the airway edge to the site when the site is outside the airway) in mi.

The airways included in this part of the analysis include the new Oak Ridge Airport traffic pattern, and airways J46, V16 and Q65.

To calculate the effective area (A) in the above equation for the CRN Site bounding building, the methodology provided in DOE Standard, DOE-STD-3014-96, (Reference 2.2-34), was used as shown below. For the BWRX-300, two separate effective areas are determined. One effective area is the Reactor Building; which is the only SC1 structure. The second effective area includes the Reactor Building, Radwaste Building and the Control Building.

$$A_{eff} = A_f(effective\ fly-in\ area) + A_s(effective\ skid\ area) \qquad \text{Equation 2.2-3}$$

$$A_f = (WS + R) * H \cot \Phi + \frac{2 * L * W_f * WS}{R} + L \qquad \text{Equation 2.2-4}$$

$$A_S = (WS + R)*S$$ Equation 2.2-5

where,

WS = the aircraft wingspan

R = the length of the diagonal of the facility

H = the height of the facility

L = the length of the facility

W_f = the width of the facility

S = the aircraft skid distance

cotΦ = the mean of the cotangent of the aircraft impact angle

The input values WS, cotΦ, and S are provided in DOE-STD-3014-96 (Reference 2.2-34), and the input values R, H, W_f, and L are facility-specific.

Based on the effective area of the Reactor Building, the probability of an aircraft crashing due to the new Oak Ridge Airport into the Reactor Building is 7.45 x 10^{-6}. Based on the combined effective area of the Reactor Building, Radwaste Building and the Control Building the probability of an aircraft crashing due to the new Oak Ridge Airport is 1.30 x 10^{-5}.

Based on the effective area of the Reactor Building, the probability of an aircraft in nearby airways crashing into the Reactor Building is 2.21 x 10^{-5}. Based on the combined effective area of the Reactor Building, Radwaste Building and the Control Building the probability of an aircraft in nearby airways crashing at some point of this combination is 3.83 x 10^{-5}.

The total hazard probabilities are determined by adding the probability due to the new Oak Ridge Airport and due to nearby airways. The total hazard probability for the Reactor Building is 2.96 x 10^{-5} per year and for the combined Reactor Building, Radwaste Building and Control Building is 5.13 x 10^{-5} per year.

2.2.2.8 Projections of Industrial Growth

Replace ESPA SSAR Section 2.2.2.8 with the following:

DOE ETTP has begun a major environmental site cleanup with the long-term goal of converting the ETTP into a private industrial park called Heritage Center Industrial Park. The cleanup activities are currently being conducted and as cleanup is completed, DOE transfers ownership of the uncontaminated buildings to the Community Reuse Organization of East Tennessee, who in turn leases this property for immediate private industrial use. Many of the buildings will be

slated for potential reuse and the remediated land will be available for new construction (Reference 2.2-26).

The City of Oak Ridge has selected a site for a new general aviation airport (Reference 2.2-50). The location is approximately 2.25 miles from the CRN Site. Potential hazards associated with this airport are evaluated in Section 2.2.2.7.

Other nearby facilities that are currently proposed or under construction are the Kairos Power Hermes Facility, Kairos Power Atlas Fuel Fabrication Facility, TRISO-X Fuel Facility, and Coqui Pharmaceutical.

The Coqui Pharmaceutical site is excluded from the discussion in the following sections as there is currently not enough information available for an analysis. However, the radiological effects from the radiopharmaceutical production facility at the Coqui Pharmaceutical site would be within regulatory offsite dose limits for routine operations and accidents. Additionally, the operations are expected to be similar to the SHINE Medical Technologies which received a construction permit from the USNRC in 2016 for a radioisotope production facility located in Janesville, Wisconsin. SHINE Medical Technologies demonstrated in its PSAR that releases of onsite chemicals were not a hazard to personnel in the facility control room. As such, chemicals stored onsite at the Coqui Pharmaceutical site would similarly not be expected to have an impact on nearby facilities, including the CRN unit.

The location and quantities of chemicals that may be stored nearby at the proposed Kairos Power Hermes Facility, the proposed Kairos Power Atlas Fuel Fabrication Facility, the proposed TRISO-X Fuel Facility, the proposed Coqui Pharmaceutical Facility, and the proposed regional airport have not yet been determined. The effects of explosions, flammable vapor clouds, and toxic chemicals for chemical storage at these nearby facilities will be reviewed in the operating license application and accounted for in the final design to the extent information regarding hazards from those nearby facilities are available.

2.2.3 Evaluation of Potential Accidents

Replace the second sentence of ESPA SSAR 2.2.3 with the following:

The potential effects of these accidents on the nuclear plant in terms of design parameters and physical phenomena were evaluated, using the guidance in RG 1.78, RG 1.91, RG 4.7, and SRP 2.2.1-2.2.2.

2.2.3.1 Determination of Potential Accidents

Replace ESPA SSAR Section 2.2.3.1 with the following:

SRP 2.2.1-2.2.2 states that design-basis events on site or in the vicinity of the nuclear plant are defined as those accidents with a probability of occurrence on the order of magnitude of 10^{-7} per year, with potential consequences sufficiently serious to affect the safety of the plant to the extent that 10 CFR 100 guidelines could be exceeded. The following accident categories are

considered in selecting design-basis events: explosions, flammable vapor clouds (delayed ignition), toxic chemicals, aircraft hazards, fires, collisions with the intake structure, and liquid spills. The postulated accidents within these categories were analyzed at the following locations:

Nearby Storage Facilities

- Facilities listed in Table 2.2-1R

Nearby Transportation Routes

- East Tennessee Natural Gas Pipelines 1 and 2
- I-40
- Oak Ridge Airport (Under Development)
- Federal Airways V16, J46 and Q65

On-Site Storage Facilities

- Substances stored on-site are identified in Table 2.2-12R.

2.2.3.1.1 Explosions

Renumber Equation 2.2-5 as Equation 2.2-6 in ESPA SSAR Section 2.2.3.1.1.

Renumber Equation 2.2-6 as Equation 2.2-7 in ESPA SSAR Section 2.2.3.1.1.

Renumber Equation 2.2-7 as Equation 2.2-8 in ESPA SSAR Section 2.2.3.1.1.

Replace the 15th and 16th paragraphs of ESPA SSAR Section 2.2.3.1.1 with the following:

The materials stored at nearby facilities (Table 2.2-2R) and potentially transported along I-40 (Table 2.2-3R) and by pipeline (Table 2.2-4) are evaluated to ascertain whether they have the potential to explode. The effects of these explosion events from external sources are summarized in Table 2.2-9R, and are described in the following subsections relative to the release source.

The nearest on-site source of potentially explosive gases is the hydrogen gas storage cylinders. Table 2.2-12R lists the quantity of hydrogen stored. The hydrogen is stored in several cylinders. Each cylinder is assumed to store 12,584 standard cubic feet (scf).

The safe separation distance between the hydrogen storage area and nearest SC1 structure is determined using the methodology in EPRI NP-5283-SR, Guidelines for Permanent BWR Hydrogen Water Chemistry Installations, September 1987 (Reference 2.2-24). Consistent with EPRI NP-5283-SR the required separation distance is determined for two different considerations. The first consideration is the required separation distance such that the SC1 structure is not adversely affected by the postulated hydrogen explosion. The second consideration is the required separation distance to air pathways into SC1 structures versus the internal diameter of the high pressure piping.

For the first consideration (vessel explosion), consistent with EPRI NP-5283-SR, it is assumed that the explosion is limited to one cylinder. The required distance is conservatively determined using the British E.S.T.C. method described in Appendix B of EPRI NP-5283-SR. This approach is conservative as it is for a structural wall design less robust than the Reactor Building wall design.

The British E.S.T.C. method uses the following relationship to determine the required separation distance:

$$R = \frac{56 * W^{1/3}}{\left[1 + \left(\frac{7{,}000}{W}\right)^2\right]^{1/6}} \qquad \text{Equation 2.2-9}$$

where:

R = Separation distance in feet

W = TNT equivalent explosive yield in lbs. For gaseous hydrogen storage, W is determined using the relationship from EPRI NP-5283-SR: 1,000 scf hydrogen = 27.1 lbs. TNT

Using the above British E.S.T.C. method for the same conditions (i.e., one cylinder fails) the required separation distance for a cylinder explosion is 142.8 feet.

The required separation distance for the second consideration (gaseous pipe break) determined using EPRI NP-5283-SR is approximately 230 feet.

The hydrogen cylinders will be located more than 230 feet from the Reactor Building and the Control Building. The transportation route to replace hydrogen cylinders will be greater than the minimum separation distance such that a cylinder explosion during transport will not adversely impact the plant.

2.2.3.1.1.1 Nearby Facilities

Replace ESPA SSAR Section 2.2.3.1.1.1 with the following:

The following were identified as facilities of concern with regard to storage of materials with the potential for explosion within the vicinity of the CRN Site (Section 2.2.2.2.2):

- Custom Foods of America, located approximately 23.6 mi (125,000 ft) from the site,
- East Tennessee Technology Park, located approximately 3 mi (16,000 ft) from the site,
- Energy Solutions Services – Bear Creek Facility, located approximately 1.6 mi (8,290 feet) from the site,
- Food Lion – Delhaize Distribution Center, located approximately 20 mi (108,000 ft) from the site,
- Linde Inc., located approximately 11 mi (57,600 ft) from the site,

- ORNL-Battelle, located approximately 4.3 mi (22,900 ft) from the site,
- Primary Products Ingredients, located approximately 11 mi (57,600 ft) from the site,
- Processed Food Corporation, located approximately 23.6 mi (125,000 ft) from the site,
- TVA – Kingston Fossil Plant, located approximately 7.7 mi (40,900 ft) from the site,
- U.S. Foodservice - Knoxville, located approximately 23.3 mi (123,000 ft) from the site,
- Weigel's #58, located approximately 3.7 mi (19,400 ft) from the site.

Each material stored at the identified offsite facilities was evaluated with respect to explosion potential. Each material was then dispositioned based on the identified physical properties of the material and whether a bounding analysis exists. The results of this evaluation are found in Table 2.2-5R (footnotes describe the bases for explosive materials not carried forward for further analysis).

A conservative analysis using the TNT equivalency methods described in Section 2.2.3.1.1 was used to determine safe distances for the identified potentially explosive materials. The results indicate that the safe distances are less than the minimum separation distances from the CRN Site power block area to the storage locations for the identified materials (Table 2.2-9R). Propane stored at the Energy Solution Services - Bear Creek Facility resulted in the largest safe distance, 2673 ft, which is less than the distance of 8,290 ft to the CRN Power Block.

Therefore, damaging overpressures from an explosion resulting from a complete failure of the total stored quantity for each material evaluated at each of the identified facilities of concern with regard to the storage of materials with the potential for explosion would not adversely affect the operation or shutdown of the CRN unit.

2.2.3.1.1.2 Nearby Transportation Routes/Roadways

Replace the 3rd and 4th sentences of the second paragraph of ESPA SSAR Section 2.2.3.1.1.2 with the following:

The results of this evaluation are found in Table 2.2-6R (footnotes describe the basis for explosive materials not carried forward for further analysis). The hazardous materials that are identified for further analysis with regard to explosion potential were butane, gasoline, hydrogen, methanol, methyl chloroform, and propane (Table 2.2-6R).

2.2.3.1.1.3 Nearby Transportation Routes/Pipelines

Renumber Equation 2.2-8 to Equation 2.2-10 in ESPA SSAR Section 2.2.3.1.1.3.

Renumber Equation 2.2-9 to Equation 2.2-11 in ESPA SSAR Section 2.2.3.1.1.3.

2.2.3.1.2 Flammable Vapor Clouds (Delayed Ignition and Jet Fire)

Replace the 1st and 2nd sentences of the 5th paragraph in ESPA SSAR Section 2.2.3.1.2 with the following:

Conservative assumptions were used in the ALOHA analyses regarding both meteorological inputs and identified scenarios for both events. Each postulated event was evaluated under a spectrum of meteorological conditions.

Replace the 7th paragraph in ESPA SSAR Section 2.2.3.1.2 with the following:

For some of the chemicals considered herein, the evaluation of possible impacts due to a flammable vapor cloud identified that these were enveloped by analyses using ALOHA. The effects of flammable vapor clouds and vapor cloud explosions from external sources are summarized in Table 2.2-10R and are described in the following subsections relative to the release source.

The nearest on-site source of potentially explosive gases is the hydrogen gas storage cylinders for the Hydrogen Water Chemistry system. Table 2.2-12R lists the maximum quantities of flammable gas (hydrogen) stored at the CRN Site. The safe separation distance between the hydrogen storage area and the nearest SC1 structures is 230 ft. The method used to evaluate the safe separation for hydrogen gas storage is described in Subsection 2.2.3.1.1.

2.2.3.1.2.1 Nearby Facilities

Replace ESPA SSAR Section 2.2.3.1.2.1 with the following:

The following were identified as facilities of concern with regard to storage of materials with the potential for formation of flammable/explosive vapor clouds within the vicinity of the CRN Site (Subsection 2.2.2.2.2):

- Custom Foods of America, located approximately 23.6 mi (125,000 ft) from the site,
- East Tennessee Technology Park, located approximately 3 mi (16,000 ft) from the site,
- Energy Solutions Services – Bear Creek Facility, located approximately 1.6 mi (8,290 feet) from the site,
- Food Lion – Delhaize Distribution Center, located approximately 20 mi (108,000 ft) from the site,
- Linde Inc., located approximately 11 mi (57,600 ft) from the site,
- ORNL–Battelle, located approximately 4.3 mi (22,900 ft) from the site;
- Primary Products Ingredients, located approximately 11 mi (57,600 ft) from the site,
- Processed Food Corporation, located approximately 23.6 mi (125,000 ft) from the site,
- TVA – Kingston Fossil Plant, located approximately 7.7 mi (40,900 ft) from the site;
- U.S. Foodservice – Knoxville, located approximately 23.3 mi (123,000 ft) from the site, and
- Weigel's #58, located approximately 3.7 mi (19,400 ft) from the site.

Each material stored at the identified offsite facilities was evaluated with respect to its potential for formation of flammable/explosive vapor clouds. Each material was then dispositioned based on the identified physical properties of the material and whether a bounding analysis exists. The results of this evaluation are found in Table 2.2-5R (for flammable/explosive materials not carried forward for further analysis, footnotes indicating the reason for the disposition are provided in the table). The materials stored at each site identified for further analysis are identified in Table 2.2-5R.

As described in Subsection 2.2.3.1.2, the ALOHA dispersion model was used to determine the distance a vapor cloud could travel to reach the LFL boundary once a vapor cloud has formed from an accidental release of the identified chemical. The results indicated that any plausible vapor cloud that could form and mix sufficiently under stable atmospheric conditions would be below the LFL boundary before reaching the CRN Site power block area (Table 2.2-10R).

A vapor cloud explosion analysis was also completed following the methodology as detailed in Subsection 2.2.3.1.2 in order to obtain safe distances. The results conclude that the safe distances (the minimum distance required for an explosion to have less than a 1 psi peak incident pressure) are less than the shortest distance to the CRN Site power block area and the storage location of these chemicals (Table 2.2-10R).

Therefore, a flammable vapor cloud with the possibility of ignition or explosion formed from the storage of chemicals at offsite facilities will not adversely affect the safe operation or shutdown of units within the CRN Site power block area.

2.2.3.1.2.2 Nearby Transportation Routes/Roadways

Replace the 4th sentence to the end of the 2nd paragraph of ESPA SSAR Section 2.2.3.1.2.2 with the following:

The materials identified for further analysis with regard to flammable vapor clouds were acrylonitrile, butane, gasoline, methanol, methyl chloroform, methyltrichlorosilane and propane (Table 2.2-6R). It was conservatively assumed that the maximum quantity of the butane and propane potentially transported on the roadway is 11,500 gallons (gal), which represents the maximum transport quantity in an MC-331 high pressure tank truck (49 CFR 173.315 and Reference 2.2-42). For gasoline, it is conservatively assumed that 8500 gal is potentially transported on I-40. Both quantities are greater than 50,000 lb which is the maximum probable solid cargo highway transport quantity identified in RG 1.91. The transported quantities for the other materials is based on the storage quantity at the associated location.

Replace the 3rd and 4th paragraphs of ESPA SSAR Section 2.2.3.1.2.2 with the following:

An analysis for the identified chemicals was conducted using ALOHA as described in Subsection 2.2.3.1.2. The results indicate that any plausible vapor cloud that could form and mix sufficiently would be below the LFL boundary before reaching the CRN Site power block area. The safe distances are less than the minimum separation distances from the CRN Site power block area to I-40 for each of the identified chemicals (Table 2.2-10R).

A vapor cloud explosion analysis was also completed as detailed in Subsection 2.2.3.1.2 to obtain safe distances. The results indicate that the safe distances, the minimum distances required for an explosion to have less than a 1 psi peak incident pressure are less than the shortest distance to the power block area to I-40 (Table 2.2-10R).

2.2.3.1.3 Toxic Chemicals

Replace the 2nd paragraph in ESPA SSAR Section 2.2.3.1.3 with the following:

Each identified chemical is evaluated based upon the chemical's properties, quantities, and distance in relation to the power block area without consideration of plant design factors, such as control room ventilation. Chemicals that lead to concentrations above the Immediately Dangerous to Life or Health (IDLH) limit at the power block area boundary will be identified.

Replace the 1st and 2nd sentences of the 3rd paragraph ESPA SSAR Section 2.2.3.1.3 with the following:

Chemicals were initially screened using the methodology in RG 1.78 to determine which warranted more detailed analyses. In selected cases, the ALOHA air dispersion model was used to predict the chemical concentrations within a toxic or asphyxiating vapor cloud as it disperses downwind for facilities and sources.

Replace the 1st sentence of the 5th paragraph ESPA SSAR Section 2.2.3.1.3 with the following:

Each postulated toxicity/asphyxiation event was evaluated under a spectrum of meteorological conditions to determine the worst-case meteorological condition.

Replace the last paragraph of ESPA SSAR Section 2.2.3.1.3 with the following:

The effects of toxic chemical releases from nearby facilities and transportation routes are summarized in Table 2.2-11R and are described in the following subsections relative to the release sources.

The effects of toxic chemical releases from onsite chemical storage are described in Subsection 2.2.3.1.3.4.

2.2.3.1.3.1 Nearby Facilities

Replace ESPA SSAR Section 2.2.3.1.3.1 with the following:

The following were identified as facilities of concern with regard to storage of materials with the potential for release of a toxic vapor cloud within the vicinity of the CRN Site (see Subsection 2.2.2.2.2):

- A.E. Staley / Tate & Lyle Manufacturing, located approximately 11 mi (58,000 ft) from the site,
- City of Maryville Wastewater Treatment Plant, located approximately 24 mi (127,700 ft) from the site,

- City of Oak Ridge Municipal Pool, located approximately 10.8 mi (57,000 ft) from the site,
- Custom Foods of America, located approximately 23.6 mi (125,000 ft) from the site,
- Diversified Scientific Services, located approximately 3.4 mi (17,800 ft) from the site,
- Duracap Asphalt Paving, located approximately 2.3 m (12,000 ft) from the site,
- East Tennessee Mechanical Contractors WTP, located approximately 10.5 mi (55,200 ft) from the site,
- East Tennessee Technology Park, located approximately 3 mi (16,000 ft) from the site,
- Energy Solutions Services – Bear Creek Facility, located approximately 1.6 mi (8,290 feet) from the site,
- First Utility District of Knox County WTP, located approximately 14.2 mi (75,100 ft) from the site,
- First Utility District of Knox County WWTP, located approximately 13.4 mi (70,700 ft) from the site
- Food Lion – Delhaize Distribution Center, located approximately 20 mi (108,000 ft) from the site,
- Fourth Creek Wastewater Treatment Plant, located approximately 22 mi (116,700 ft) from the site,
- Hallsdale Powell Utility District Melton Hill WTP, located approximately 18.2 mi (96,000 ft) from the site,
- Harrison Construction – Gallaher Concrete Plant, located approximately 3 mi (16,000 ft) from the site,
- Linde, Inc., located approximately 11 mi (57,600 ft) from the site,
- NAC Philotechnics – Horizon Center, located approximately 4.9 mi (26,000 ft) from the site,
- Oak Ridge WTP, located approximately 10.5 mi (55,000 ft) from the site,
- ORNL–Battelle, located approximately 4.3 mi (22,900 ft) from the site,
- ORNL-UCOR, located approximately 4.9 miles north of the CRN site,
- Primary Products Ingredients, located approximately 11 mi (57,600 ft) from the site,
- Processed Food Corporation, located approximately 23.6 mi (125,000 ft) from the site,
- Tellico Area Service System Water Treatment Plant, located approximately 21.8 mi (115,000 ft) from the site,
- TVA – Kingston Fossil Plant, located approximately 7.7 mi (40,900 ft) from the site,
- TVA – Melton Hill Hydro Plant, located approximately 4.7 mi (24,500 ft) from the site,
- U.S. Foodservice – Knoxville, located approximately 23.3 mi (123,000 ft) from the site,
- Weigel's #58, located approximately 3.7 mi (19,400 ft) from the site.
- West Knox Utility District WTP, located approximately 9.1 (48,000 ft) from the site,
- West Knox Utility District WWTP, located approximately 14.4 mi (75,900 ft) from the site, and
- Yale Security Inc., located approximately 9.5 miles (50,000 ft) from the site.

Each material stored at the identified offsite facilities was evaluated with respect to its potential for formation of a toxic vapor cloud. Each material was then dispositioned based on the identified

physical properties of the material and whether a bounding analysis exists. The results of this evaluation are found in Table 2.2-5R (for toxic materials not carried forward for further analysis, footnotes indicating the reason for the disposition are provided in the table). Materials identified for further analysis are identified in Table 2.2-5R.

Table 2.2-11R shows the chemicals from Table 2.2-5R that were carried over for further evaluation. For each chemical, Table 2.2-11R shows the quantity analyzed, the associated IDLH limit, the distance from the source to the CRN Power Block in feet, and the distance from the source to where the concentration is less than the IDLH limit. In some cases, where the RG 1.78 simplified calculation methodology was used, Table 2.2-11R identifies that the distance from the source to the IDLH limit is less than the distance from the source to the CRN Site.

As described in Subsection 2.2.3.1.3, some of the identified chemicals were analyzed using the ALOHA dispersion model to determine whether the formed vapor cloud would reach the CRN Site power block area with concentrations greater than the determined toxicity limit.

For those chemicals that are gases under the atmospheric release conditions for the given scenario the distances to the IDLH/asphyxiating or other determined toxicity limits were calculated following a 10-min release from the largest storage. For those chemicals that are liquids under the atmospheric release conditions for the given scenario the release scenario in each of these analyses includes the total loss of the largest vessel, resulting in an unconfined 1-cm thick puddle.

In the case of each of the atmospheric gases analyzed, the distances to the IDLH/asphyxiating or other determined toxicity limit were calculated. The results indicate that any plausible toxic vapor cloud that could form would be below the IDLH or other identified toxicity limit before reaching the CRN Site power block area (Table 2.2-11R).

Therefore, the formation of a toxic vapor cloud following an accidental release of the analyzed hazardous materials stored on site will not adversely affect the safe operation or shutdown of units within the CRN Site power block area (Table 2.2-11R).

2.2.3.1.3.2 Nearby Transportation Routes/Roadways

Replace ESPA SSAR Section 2.2.3.1.3.2 with the following:

The nearest approach from I-40 to the CRN Site power block area is approximately 1.1mi (5800 ft). Table 2.2-3R details the hazardous materials potentially transported on I-40. The materials identified for further analysis with regard to formation of toxic vapor clouds were acrylonitrile, anhydrous ammonia, argon, butane, carbon dioxide, chlorine, chlorine dioxide, gasoline, helium, HFC-134A, hydrochloric acid, hydrofluoric acid, hydrogen chloride, methanol, methyl chloroform, methyltrichlorosilane, nitric acid, nitric oxide, nitrogen, nitrogen dioxide, propane, and sulfur dioxide (Table 2.2-6R). It is conservatively assumed that the maximum quantity of the anhydrous ammonia and butane potentially transported on the roadway is 11,500 gal, which is the maximum transport quantity in an MC-331 high pressure tank truck (49 CFR 173.315 and Reference 2.2-42). For chlorine, a maximum transport quantity of 22 T is

assumed (Reference 2.2-18). For hydrochloric acid and nitric acid, it was conservatively assumed that the maximum quantity potentially transported on the roadway is 6000 gal, which is the maximum transport quantity in an MC-312/DOT412 Corrosive Tanker (Reference 2.2-42).

For gasoline, it was conservatively assumed that 8500 gal is potentially transported on I-40. For argon, carbon dioxide, helium, HFC-134A, methanol, methyl chloroform, propane and sulfur dioxide a transported quantity of 50,000 lbs is assumed which is the maximum probable cargo highway transport quantity identified in RG 1.91. The transported weights of acrylonitrile, chlorine dioxide, hydrofluoric acid, hydrogen chloride, methyltrichlorosilane, nitric oxide, and nitrogen dioxide are based on the quantity stored at the associated location.

An analysis for the identified chemicals was the simplified approach in RG 1.78, and, where necessary, using ALOHA as described in Subsection 2.2.3.1.3. The results indicated that, except for anhydrous ammonia, chlorine, hydrochloric acid and nitric acid, the distances to the identified toxicity limit for any plausible toxic vapor cloud that could form following an accidental release at the closest approach from the transportation route (I-40) are less than the minimum separation distances from the CRN Site power block area to I-40 (Table 2.2-11R).

A release of anhydrous ammonia results in a distance of 13,728 ft to the toxicity endpoint and a release of chlorine results in a distance of 23,760 ft to the toxicity endpoint. Both determined distances to the toxic endpoints are greater than the distance of 5800 ft to the CRN Site power block area. Hydrochloric acid and nitric acid were not able to be screened using the methodology in RG 1.78, Appendix A.

Add new Section 2.2.3.1.3.4:

2.2.3.1.3.4 On-Site Storage

The identified onsite chemicals are listed in Table 2.2-12R; which, for each chemical, lists the on-site location and the quantity stored. Each chemical is dispositioned relative to control room habitability, flammability, or explosive concern. The disposition for each chemical is summarized in Table 2.2-13R. Table 2.2-13R shows that the majority of the chemicals are not toxic, flammable, or explosive.

Hydrogen is analyzed for explosion concern as described in Subsection 2.2.3.1.1. Cryogenic nitrogen can pose a potential asphyxiation concern for the control room operators. This potential was evaluated using the HABIT computer code and determined that the atmosphere in the Control Room would not be reduced to an oxygen deficient environment. For chemicals with IDLH values listed in Table 2.2-13R, the effects of toxic vapors or gases and their potential for incapacitating the control room operators were evaluated and determined that these were not a hazard to the operators in the Control Room.

Therefore, the formation of a toxic vapor cloud following an accidental release of hazardous materials stored on site will not adversely affect the safe operation or shutdown of the unit (Table 2.2-13R).

This evaluation is based on the chemicals identified at this time. The effects of explosions, flammable vapor clouds, and toxic chemicals from onsite chemical storage will be reviewed in the operating license application and accounted for in the final design.

2.2.3.1.4 Fires

Replace ESPA SSAR Section 2.2.3.1.4 with the following:

As discussed in Subsection 2.2.3.1.3.4, there are no concerns with fire from chemicals stored on site. Onsite fuel storage facilities are designed in accordance with applicable fire codes, and plant safety is not jeopardized by fires or smoke in these areas. A description of the fire protection system is presented in Subsection 9.5.1.

Fire and smoke from accidents at nearby homes, industrial facilities, transportation routes, or from area forest or brush fires, do not jeopardize the safe operation of the unit due to the separation distance of potential fires from the unit. A description of the Control Building Heating, Ventilation, and Cooling System is presented in Subsection 9.4.1.

External accidents were considered in the vicinity of the CRN Site that could lead to high heat fluxes or smoke, and nonflammable gas or chemical-bearing clouds from the release of materials as a consequence of fires. Fires from nearby facilities and fires from transportation accidents and pipelines are evaluated as events that could lead to high heat fluxes or to the formation of such clouds.

Those chemicals stored at nearby facilities and transported by roadway on I-40, are evaluated in Subsection 2.2.3.1.2 for potential effects of accidental releases leading to a delayed ignition of any formed vapor cloud. For each of the stored or transported materials evaluated, the results indicate that any formed vapor cloud will dissipate below the LFL before reaching the CRN Site power block area boundary. Therefore, it is not expected that there would be any hazardous effects to units at the CRN Site from fires or heat fluxes associated with the storage of chemicals at nearby facilities or from the transport of chemicals on I-40.

Furthermore, a heat flux analysis for a pipeline break indicates that there would be no effect on the safe operation or shutdown of units within the CRN Site power block area. ALOHA is used to determine the limiting heat flux from a jet fire due to a natural gas pipeline break. The results of the jet fire analysis conclude that the safe distance (i.e., the distance to 5 kW/m^2) for the 6-in. pipeline (Pipeline 1) of 312 ft is less than the separation distance, 5800 ft, between the CRN Site power block area and the pipeline break. The safe distance for the 22-in. pipeline (Pipeline 2) of 1203 ft is less than the separation distance, 15,800 ft.

Therefore, it is not expected that there would be any hazardous effects to units at the CRN Site from fires or heat fluxes associated with the storage of chemicals at nearby facilities, the transport of chemicals on I-40, or from the East Tennessee Natural Gas Pipelines evaluated.

2.2.3.2 Effects of Design-Basis Events

Replace ESPA SSAR Section 2.2.3.2 with the following:

Evaluations were performed of potential hazards nearby and on the CRN Site. Except where noted, these evaluations concluded that potential accidents involving explosions, flammable vapor clouds, collisions with intake structures, and liquid spills do not pose a threat to the CRN Site.

Table 2.2-1R Description of Facilities - Products and Materials
(Sheet 1 of 3)

Facility	Concise Description	Primary Function	Major Products
A. E. Staley Manufacturing Company-Loudon / Tate & Lyle, Loudon [(b)]	Food ingredient development	Develop ingredients for food and beverages	Food ingredients
City of Maryville Wastewater Treatment Plant	Wastewater treatment plant	Wastewater treatment	Clean water Residual biosolids product that can be used for soil amendment
City of Oak Ridge Municipal Pool	Municipal swimming pool	Public access to outdoor swimming	Recreation
Custom Foods of America	Products for the food industry	Food products for restaurants and convenience stores	Ready to eat food products
Diversified Scientific Services, Inc.	Radioactive waste treatment	Operate waste treatment facilities	Waste treatment
Duracap Asphalt Paving	Construction services	Asphalt paving, grading and drainage, site utilities	Asphalt paving
East Tennessee Mechanical Contractors (ETMC) WTP	Construction company	Facilities management, General construction, Mechanical design and construction	Construction management
East Tennessee Technology ParkEast Tennessee Technology Park - UCOR LLC-UCOR Rollup©	Managing hazardous wastes	Managing wastes and site remediation	Site cleanup for eventual site transition to public use
Energy Solution Services, Bear Creek Facility	Radioactive waste processing facility	Process radioactive waste	Processed waste materials
First Utility District of Knox County WTP	Water treatment plant	Water treatment and distribution	Drinking water supply
First Utility District of Knox County WWTP	Wastewater treatment plant	Wastewater treatment	Clean water
Food Lion - Delhaize DC #6	Food retail	Food retail to the general public	Food

Table 2.2-1R Description of Facilities - Products and Materials
(Sheet 2 of 3)

Facility	Concise Description	Primary Function	Major Products
Fourth Creek Wastewater Treatment Plant	Wastewater treatment plant	Wastewater treatment	Clean water
Hallsdale Powell Utility District - Melton Hill WTP	Water treatment plant	Water treatment and distribution	Drinking water supply
Harrison Construction, Gallaher Concrete Plant	Construction materials	Provide aggregates, ready mix concrete, etc.	Aggregates, Ready Mix Concrete
Knoxville PDC – Volkswagen Group of America	Car Distribution Service	Car distribution	Car distribution for retail
Linde, Inc.	Gas and equipment supplier	Provide industrial and specialty gases	Industrial and specialty gases. Provide associated supply systems
NAC Philotechnics – Horizon Center	Radioactive and mixed waste processing facility	Process radioactive waste	Processed waste materials
Oak Ridge National Laboratory	Federal government science and energy laboratory	Federal sponsored unique research and development	Government research and development laboratory
Oak Ridge National Laboratory - UCOR LLC - UCOR Rollup	Oak Ridge National Laboratory Cleanup	Deactivation and demolishing	Site remediation
Oak Ridge Water Treatment Plant	Water treatment plant	Water treatment and distribution	Drinking water supply
Primary Products Ingredients Americas, LLC	Food ingredient development	Develop ingredients for food and beverages	Corn syrup, crystalline fructose, fuel ethanol
Processed Food Corporation	Products for the food industry	Food products for restaurants and convenience stores	Ready to eat food products
Tellico Area Service System WTP	Water treatment plant	Water treatment and distribution	Drinking water supply
TVA – Kingston Fossil Plant	Coal-fired power plant	Power generation	Electrical power
TVA – Melton Hill Hydro Plant	Hydroelectric power plant	Power generation	Electrical power

Table 2.2-1R Description of Facilities - Products and Materials
(Sheet 3 of 3)

Facility	Concise Description	Primary Function	Major Products
U.S. Foodservice - Knoxville	Restaurant supplier	Food distribution to restaurants	Food storage and distribution
Weigel's #58	Convenience Store	Dispense fuel and other commodities	Gasoline, propane, diesel
West Knox Utility District WTP	Water treatment plant	Water treatment and distribution	Drinking water supply
West Knox Utility District WWTP	Wastewater treatment plant	Wastewater treatment	Clean water
Yale Security Inc.	Manufacture commercial locks and hardware	Manufacturing, including metalworking, electroplating, polishing, etc.	Commercial locks and hardware

Table 2.2-2R Nearby Facilities Chemical Storage
(Sheet 13 of 13)

Chemical	Facility/Location	Quantity (lbs)[(a)] (unless otherwise noted)	Toxicity Limit (IDHL) [(b)]

a) Where a capacity number was obtained from the Superfund Amendments and Reauthorization Act (SARA) Title III, Tier II report, or the RMP report, the upper range number is shown and was used in the analysis.

b) Immediately Dangerous to Life or Health. “Not Available” indicates that there has not been a toxicity limit established for this chemical.

c) Gasoline does not have an identified IDLH. The Threshold Limit Value-Short Term Exposure Limit TLV-STEL is 500 ppm; the Threshold Limit Value-Time-weighted Average (TLV-TWA) is 300 ppm; and the Protective Action Criteria (PAC) PAC-2 guideline is 1000 ppm for gasoline. For the analyses, n-Heptane is used as a surrogate and has an IDLH of 750 ppm. This selection is conservative given the PAC-2 guideline most closely correlates with the definition of IDLH.

Notes:

Sulfur Dioxide	50,000[c]	100 ppm

Table 2.2-3R Hazardous Materials Potentially Transported Along I-40 in the CRN Site Vicinity
(Sheet 2 of 2)

Chemical	Quantity (lbs)[(a)]	Toxicity Limit (IDHL)

a) Quantity is in lbs unless otherwise specified.

b) Gaseous hydrogen is not considered as a toxicity concern due to the extreme buoyancy. That is, hydrogen gas would rise extremely rapidly and not cause a travelling vapor cloud.

c) Per RG 1.91, the maximum probable cargo for a single highway truck is 50,000 lb and used for the quantity transported unless a more appropriate value could be determined.

d) Chlorine gas quantity determined from The Chlorine Institute Bulk Storage of Liquid Chlorine (Reference 2.2-18).

e) Hydrogen gas quantity determined from Weldship Corporation super jumbo tube product specifications (the largest size tube available) (Reference 2.2-29).

f) The maximum highway cargo capacity, 50,000 lb provided in RG 1.91 was converted to gal for gasoline.

g) The maximum capacity of MC-312/DOT412 corrosive tanker is 6000 gal.

h) Transport quantity is assumed to be the same as the site storage quantity.

i) The maximum capacity of MC-331 high pressure tank truck is 11,500 gal per 49 CFR 137.315.

Notes:

Yale Security						
Chlorine	8,000	10 ppm	7600 mm Hg @ 86°F (6.8 atm)	No	9.5	Toxicity Analysis[(a)]

Notes:

a) Per RG 1.78, chemicals stored or situated at distances greater than 5 miles from the plant need not be considered because atmospheric dispersion will dilute and disperse the incoming plume such that toxic limits will never be reached. The exceptions are those chemicals considered very hazardous substances per 40 CFR 68.130, chemicals such as ammonia, chlorine, and sulfur dioxide. These very hazardous substances require an offsite consequence analysis for Risk Management Programs required under the Clean Air Act consisting of a worst-case release scenario and/or alternative release scenarios with a toxic endpoint evaluated at facilities greater than 5 miles from Clinch River (as defined in 40 CFR 68.25).

b) According to RG 1.78, if a substance's vapor pressure is below 10 torr (approximately 10 mm Hg); the vapor pressure is sufficiently low such that the formation of a vapor cloud is not a likely event. Therefore, an air dispersion hazard is not a likely exposure route.

c) Sodium hydroxide solution is a dark, thick liquid that is a severe irritant and is toxic and corrosive. It will not burn under typical fire conditions and is normally stable but it unstable at elevated temperatures and pressure.

d) Calcium Chloride is a white to off-white solid in solution and does not burn. No IDLH, LEL, UEL, AEGLs, or ERPGs are established and the protective action criteria (PAC-1) is 3 mg/m3, PAC-2 is 33 mg/m3 and PAC-3 is 200 mg/m3. An air dispersion hazard is not a likely exposure route.

e) Fly Ash is a noncombustible solid and the vapor pressure is not applicable. It is stable under most conditions, thus, an air dispersion hazard is not a likely route of exposure.

f) Lead, in its pure form, is a noncombustible solid and, therefore, has a very low vapor pressure. No toxicity limit in air is established for this chemical. Therefore, an air dispersion hazard is not a likely route of exposure.

g) Limestone is a noncombustible solid and has a very low vapor pressure. No toxicity limit is established for this chemical; therefore an air dispersion hazard is not a likely route of exposure.

Table 2.2-5R Offsite Chemical Storage - Disposition
(Sheet 14 of 15)

Chemical	Quantity (lbs)	Toxicity Limit (IDLH)	Vapor Pressure	Flammable/ Explosive? Yes or No	Distance to CRN (miles)	Disposition

h) Nonylphenol Ethoxylates (NPE) is a colorless liquid or white solid with a mild odor. It does not react rapidly with air or water and no toxicity limit is established for this chemical, therefore an air dispersion hazard is not a likely route of exposure.

i) Considered to be equivalent to Oils for hazard analysis.

j) The facility does not specify if this substance is in an aqueous solution or is anhydrous. Anhydrous is assumed.

k) 95% limestone (CAS 1317653) and 5% liquid asphalt (CAS 8052424). Data is for liquid asphalt. Not listed in RG 1.78.

l) An advanced super adsorbent media for containing aqueous matter in critical wastes. The specialty adsorbent is capable of adsorbing as much as 350 times (by weight) of water.

m) 3% arsenic acid CAS 7778394, 4% chromium CAS 7440473, 2% Copper oxide, 91% sour water CAS 7732185.

n) Green dyed wood fibers, biodegradable fibers, minerals and a proprietary binder mixture.

o) Similar to asphalt cement.

p) Oxygen is a colorless, odorless and tasteless gas. It will support life. It is noncombustible, but will actively support the burning of combustible materials. Pure oxygen is nonflammable.

q) Peracetic acid is a colorless liquid with a strong, pungent acrid odor. Used as a bactericide and fungicide, especially in food processing; as a reagent in making caprolactam and glycerol; as an oxidant for preparing epoxy compounds; as a bleaching agent; a sterilizing agent. No toxicity limit is established for this chemical; thus, an air dispersion hazard is not a likely route of exposure

r) Silica, or silicon dioxide (SiO_2) naturally occurs in both crystalline and amorphous forms.

s) ULTRACK is an asphalt emulsion that yields a fast setting, non-tack coat. It may also be used in prime coat applications. The product is made primarily of asphalt (CAS 8052-42-4) and water. No toxicity limit is established for this chemical; thus, an air dispersion hazard is not a likely route of exposure.

t) Vinyl Acetate is clear colorless liquid which is slightly soluble in water. Used to make adhesives, paints, and plastics. No toxicity limit is established for this chemical; thus, an air dispersion hazard is not a likely route of exposure

u) Urea is solid, odorless, white crystals or pellets that are noncombustible. No toxicity limit is established for this chemical; thus, an air dispersion hazard is not a likely route of exposure.

Table 2.2-5R Offsite Chemical Storage - Disposition
(Sheet 15 of 15)

Chemical	Quantity (lbs)	Toxicity Limit (IDLH)	Vapor Pressure	Flammable/ Explosive? Yes or No	Distance to CRN (miles)	Disposition

v) Ferric sulfate is a yellow crystalline solid or a grayish-white powder. It is used for water purification, and as a soil conditioner. No toxicity limit is established for this chemical; thus, an air dispersion hazard is not a likely route of exposure.

Sulfur Dioxide	100 ppm	2432 mm Hg	Not Flammable	None Listed	Toxicity Analysis[(b)]

a) Single or multiple storage locations; maximum evaluated quantity greater than 50,000 lbs; maximum evaluated safe distance is greater than 1 mi for toxicity and less than 1 mi for flammable/explosive evaluations.

b) Single or multiple storage locations (For single storage location, assumed transport quantity is equivalent to maximum storage quantity. For multiple storage locations, assumed transport quantity is either based on RG 1.91 or the maximum tanker size); maximum evaluated safe distance is less than 1 mi for each accident category evaluated.

c) Multiple storage location; maximum evaluated quantity is less than 50,000 lbs; and maximum evaluated safe distance is greater than 1 mi.

d) Due to the buoyant nature of gaseous hydrogen such as in tube trailers, gaseous hydrogen is not considered to present an outdoor vapor cloud explosion potential or toxic threat to the control room.

e) Studies have shown that an ammonia-air mixture does not ignite at less than 1562°F. Conditions favorable for ignition are seldom encountered during normal operations due to high ignition temperature required.

Table 2.2-7R Aircraft Operations - Significance Factors
(Sheet 2 of 2)

Airport	Projected Number of Operations per Year [a]	Distance from Plant, D (statue mile (mi))	Significance Factor [b]

a) The values for airports with available FAA Terminal Aerodrome Forecasts(TAF) data (Reference 2.2-35) operations are projected 2050 APO values (where the projected number of operations is not derived from FAA TAF data, the data is obtained from Reference 2.2-7).

b) D2 movements per year for sites within 5 to 10 miles and 1000D2 movements per year for sites outside 10 miles where D is the distance from the CRN Site to the airport.

c) Conservatively, except for Meadowlake, for airports located between 5 and 10 miles of the CRN Site the significance factor was based on the distance of 5 miles.

d) Private airport with four single engine plane based. Permission is required to land.

e) Private airport with two single engine planes based.

f) Private airport with one single engine planes based. Permission is required to land.

g) Private airport with four single engine planes based. Permission is required to land.

h) Private airport with thirty four single engine planes and 3 multi-engine planes based. 11,000 operations reported for 12 months ending 12/31/2022.

i) Private airport with twenty two single engine planes based. 7,118 general aviation and 2,007 general aviation itinerant operations reported.

j) Private airport with nine single engine planes based. No operations reported.

k) Oak Ridge Airport operation values are from Reference 2.2-50, the projected number of flights is for the year 2040.

l) Conservatively, for airports located between 10 and 15 miles of the CRN Site the significance factor was based on the distance of 10 miles.

(Sheet 3 of 3)

Source	Chemical Evaluated	Quantity Analyzed	Heat of Combustion (Btu/lb)	Distance to CRN Power Block (ft)	Safe Distance to Explosion to have less than 1 psi of Peak Incident Pressure (ft)

a) Transport quantity for a super jumbo tube (Reference 2.2-29).

b) Quantity of natural gas released over 5 seconds after a postulated pipe rupture.

c) Enveloped by explosion analyses of 170,000 lbs of Anhydrous Ammonia; which determined a distance of 270.9 feet to a pressure of 1 psi. Analysis of 9,999 lbs of Anhydrous Ammonia determined a distance of 105.3 feet to a pressure of 1 psi.

d) The quantity of Anhydrous Ammonia stored at Primary Products Ingredients is approximately 10% greater than that analyzed(c). The distance from Primary Products Ingredients to the CRN Site (57,922 feet) is much farther than the distance to a pressure of 1 psi (270.9 feet).

e) Enveloped by gasoline explosion at Weigel's #58.

f) Enveloped by propane explosion at Energy Solution Services, Bear Creek Facility.

a) Enveloped by other analysis of Anhydrous Ammonia release scenarios. Analyses of 170,000 lbs of Anhydrous Ammonia determined a distance of 924 feet to LFL (with F stability class and two m/s) and 2601 feet to a pressure of 1 psi from a VCE (with F stability class and one m/s). Analysis of 9,999 lbs of Anhydrous Ammonia determined a distance of 345 feet to LFL and 918 feet to a pressure of 1 psi from a VCE (with F stability class and one m/s).

b) Worst-case scenario meteorological condition is F stability class at one m/s.

c) The quantity of Anhydrous Ammonia stored at Primary Products Ingredients is approximately 10% greater than that analyzed(a). The distance from Primary Products Ingredients (57,922 feet) is much farther than the distance to LFL (924 feet) and the distance to a pressure of 1 psi from a VCE (2601 feet).

d) Worst-case scenario meteorological condition is B stability class at 1.5 m/s.

e) Worst-case scenario meteorological condition is D stability class at 5.5 m/s.

Table 2.2-10R Design Basis Events - Flammable Vapor Clouds (Delayed Ignition) Deflagration and Detonation and Jet Fire (Sheet 3 of 3)

Source	Chemical Evaluated	Quantity Analyzed(h)	Distance to CRN Power Block (ft)	Distance to LFL (ft)	Safe Distance for Vapor Cloud Explosion (VCE) to have less than 1 psi of Peak Incident Pressure (ft)	Jet Fire – Distance to 5 kW/m^2 (ft)

f) Quantity of natural gas (as methane) released from a break in the natural gas pipeline under worst case meteorological condition for deflagration scenario; assumed pipeline length of 200 times the diameter; pressure 734.7 pounds per square inch atmosphere (psia); complete break; and connected to infinite source (Subsection 2.2.3.1.2.3).

g) Quantity of natural gas (as methane) released from a break in the natural gas pipeline under worst case meteorological condition for detonation scenario; assumed pipeline length of 200 times the diameter; pressure 734.7 psia; complete break; and connected to infinite source. (Subsection 2.2.3.1.2.3)

h) Where a capacity number was obtained from the Superfund Amendments and Reauthorization Act (SARA) Title III, Tier II report, the upper range number is shown and was used in the analysis.

i) Enveloped by analysis of transportation release of 11,500 gal (57,367 lb) of Butane based on less mass and similar (or smaller) heat of combustion. Thus, the distance to LFL and distance to pressure of 1 psi from a VCE will be less than the distance to the CRN Power Block.

j) Enveloped by analysis of transportation gasoline accident.

k) The gasoline is stored underground in three tanks at Weigel's #58 convenience store (Plus 89 Ethanol, Premium 93 Ethanol, and Regular 87 Ethanol). The quantity considered is the total stored quantity and not the quantity in each tank. Weigels uses underground gasoline tanks for customer delivery at the convenience store (i.e., a gas station). The underground tanks are not pressurized and do not present a vapor cloud explosion concern.

a) Worst-case scenario meteorological condition is F stability class at one meter per second (m/s).

b) Asphyxiation Limit.

c) Worst-case scenario meteorological condition is F stability class at three m/s.

d) Chemical screened in accordance with RG 1.78, Appendix A, and determined that the quantity stored/transported is less than that which would result in exceeding the IDLH at the CRN Power Block.

e) Gasoline does not have an identified IDLH. The Threshold Limit Value-Short Term Exposure Limit (TLV-STEL) is 500 ppm; the Threshold Limit Value-Time-weighted Average (TLV–TWA) is 300 ppm; and the Protective Action Criteria (PAC) PAC-2 guideline is 1000 ppm for gasoline. For the analyses, n-Heptane is used as a surrogate and has an IDLH of 750 ppm. This selection is conservative given the PAC-2 guideline most closely correlates with the definition of IDLH.

Table 2.2-11R Design-Basis Events - Toxic Vapor Clouds
(Sheet 5 of 6)

Source	Chemical	Quantity Analyzed[(n)]	IDHL Limit	Distance to CRN Power Block (ft)	Distance to IDLH (ft)

f) Enveloped by toxic hazard analyses of Chlorine release. Analysis of 24,999 lbs of Chlorine release determined a distance of 20,064 feet to the IDLH. Analysis of 10,000 lbs of Chlorine release determined a distance of 15,312 feet to the IDLH.

g) Enveloped by toxic hazard analyses of Anhydrous Ammonia release. Analysis of 170,000 lbs of Anhydrous Ammonia release determined a distance of 21,648 feet to the IDLH. Analysis of 9,999 lbs of Anhydrous Ammonia release determined a distance of 6,336 feet to the IDLH. Worst-case scenario meteorological condition is F stability class at one meter per second (m/s).

h) Worst-case scenario meteorological condition is D stability class at 5.5 m/s.

i) The quantity of Anhydrous Ammonia stored at Primary Products Ingredients is approximately 10% greater than that analyzed. The distance from Primary Products Ingredients (57,922 feet) is much farther than the distance to the IDLH (21,648 feet).

j) The toxicity limit at the CRN Site power block area is exceeded.

k) The toxicity limit at the CRN Site power block area is exceeded.

l) The distance to the TLV-STEL is 843 feet and the distance to the TLV-TWA is 1089 feet.

m) Quantity of natural gas (as methane) released from a break in the natural gas pipeline under worst case meteorological condition for the toxic vapor cloud scenario; assumed pipeline length of 200 times the diameter; pressure 734.7 pounds per square inch atmosphere (psia); complete break; and connected to infinite source. (Subsection 2.2.3.1.2.3)

n) Where a capacity number was obtained from the Superfund Amendments and Reauthorization Act (SARA) Title III, Tier II report, the upper range number is shown and was used in the analysis.

o) Enveloped by toxic hazard analyses of Nitric Acid release. Analysis of 499,999 lbs of Nitric Acid release determined a distance of 15,312 feet to the IDLH with worst-case scenario meteorological condition of D stability class at 5.5 m/s. Analysis of 74,826 lbs of Nitric Acid release determined a distance of 5,280 feet to the IDLH with worst-case scenario meteorological condition of F stability class at three m/s.

p) The toxicity limit at the CRN Site power block area is exceeded.

Table 2.2-11R Design-Basis Events - Toxic Vapor Clouds
(Sheet 6 of 6)

Source	Chemical	Quantity Analyzed[(n)]	IDHL Limit	Distance to CRN Power Block (ft)	Distance to IDLH (ft)

q) The toxicity limit at the CRN Site power block area is exceeded.

r) Enveloped by hazard analysis of release of 9,999 lb of liquid nitrogen, which showed a limiting distance to the asphyxiation level at 489 feet.

Table 2.2-13R On-Site Chemical Evaluation
(Sheet 1 of 2)

Chemical/Material (Formula/Trade/State)	Toxicity Limit (IDLH)	Flammable/ Explosive?	Disposition
Cryogenic Nitrogen	Asphyxiant	No / No	Toxic analysis (asphyxiation) performed and found to not impact MCR habitability.
Hydrogen	Asphyxiant	Yes / Yes	Toxic evaluation (asphyxiation) performed and found to not impact MCR habitability. Safe separation distance due to an explosion is provided in Subsection 2.2.3.1.1
Standby Diesel Generator (SDG) Fuel Oil (FO)	None established	Yes (Varies) / No	No further analysis required (1)
Diesel Driven Fire Pump Fuel Oil (FO)	None established	Yes (Varies) / No	No further analysis required (1)
Turbine Lubricating Oil (LO)	None established	Yes (Varies) / No	No further analysis required (1)
Sodium Hypochlorite (10 to 15% Solution)	10 ppm (as Chlorine)	No / No	Toxic evaluation performed and found to not impact MCR habitability.
Sodium Bisulfite for CWS Discharge (40% Solution)	None established	No / No	No further analysis required.
Sulfuric Acid for CWS	15 mg/m^3	No / No	Toxic evaluation performed and found to have no impact to MCR habitability.
Sodium Bisulfite for Demineralized Water Production (30% Solution)	None established	No / No	No further analysis required.
ChemTreat CL1355 for CWS	None established	No / No	No further analysis required.
ChemTreat CL1355 for Demineralized Water Production	None established	No / No	No further analysis required.
ChemTreat CL5633 for Demineralized Water System Cleaning	None established	No / No	No further analysis required.

Table 2.2-13R On-Site Chemical Evaluation
(Sheet 2 of 2)

Chemical/Material (Formula/Trade/State)	Toxicity Limit (IDLH)	Flammable/ Explosive?	Disposition
Sodium Hydroxide (25% solution) for Demineralized Water System Cleaning	10 mg/m^3	No / No	Toxic evaluation performed and found to not impact MCR habitability.
Sodium Hypochlorite for Demineralized Water System Cleaning	10 ppm (as Chlorine)	No / No	Toxic evaluation performed and found to not impact MCR habitability.
Gasoline	750 ppm	Yes / Yes	On-site gasoline storage tank location has not been determined. Final location will provide adequate separation distance per RG 1.91.
Propylene Glycol	None established	No / No	No further analysis required.
R-134a (Tetrafluoroethane)	Asphyxiant	No / No	Toxic evaluation (asphyxiation) performed and found to not impact MCR habitability.
Na_2Pt (OH)6(Noble Metal Solution)	None established	No / No	No further analysis required.
Depleted Zinc Oxide (DZO)	None established	No / No	No further analysis required.
R410a (used in mini-split AC units)	None established; asphyxiant	No / No	Toxic evaluation (asphyxiation) performed and found to not impact MCR habitability.

1) A fluid with an extremely low vapor pressure will not explode per NFPA 422 (Reference 2.2-81) which states that the vapor space in tanks storing low vapor pressure liquids is normally too lean to burn. The vapor pressure of diesel fuel is low enough such that the vapor concentration above the liquid (0.36%) is significantly lower than the LFL (1.3%). As a result the air-gas mixture is expected to be too lean to ignite and/or explode. Similarly, kerosene grade fuel ordinarily has a low tendency to vaporize, and in a closed tank, the fuel vapor and air mixture can be too lean to burn.

Replace Figure 2.2-1 with the following:

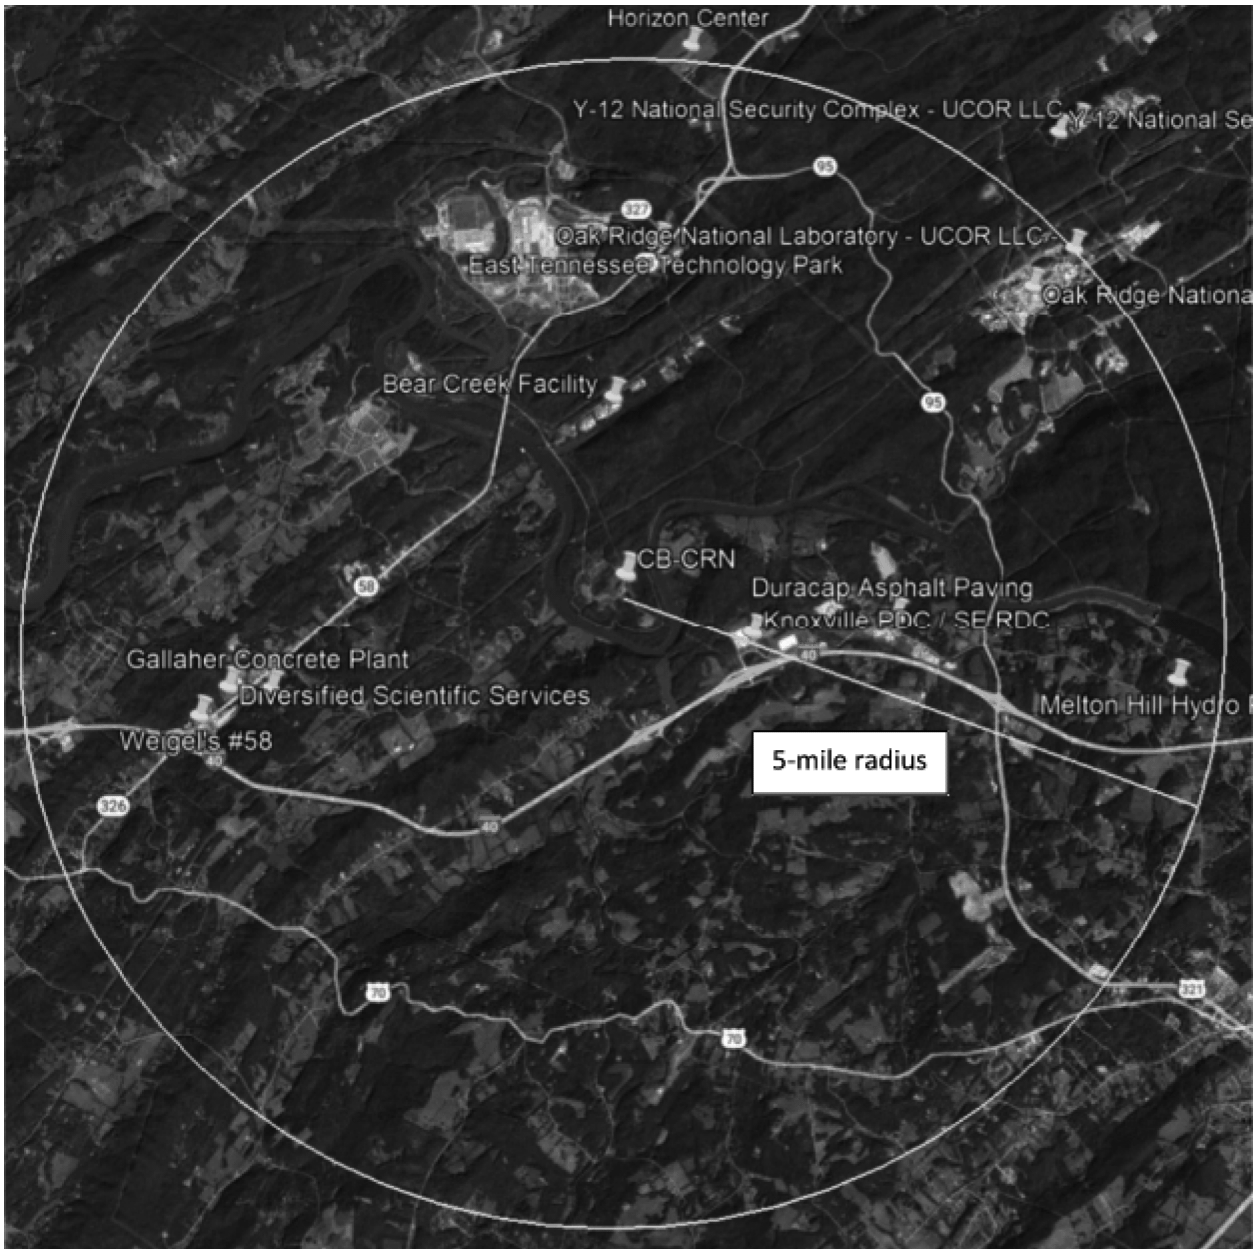

Figure 2.2-1R Identified Industrial Facilities Nearby the Clinch River Nuclear Site (5 mile radius)

Replace Figure 2.2-3 with the following:

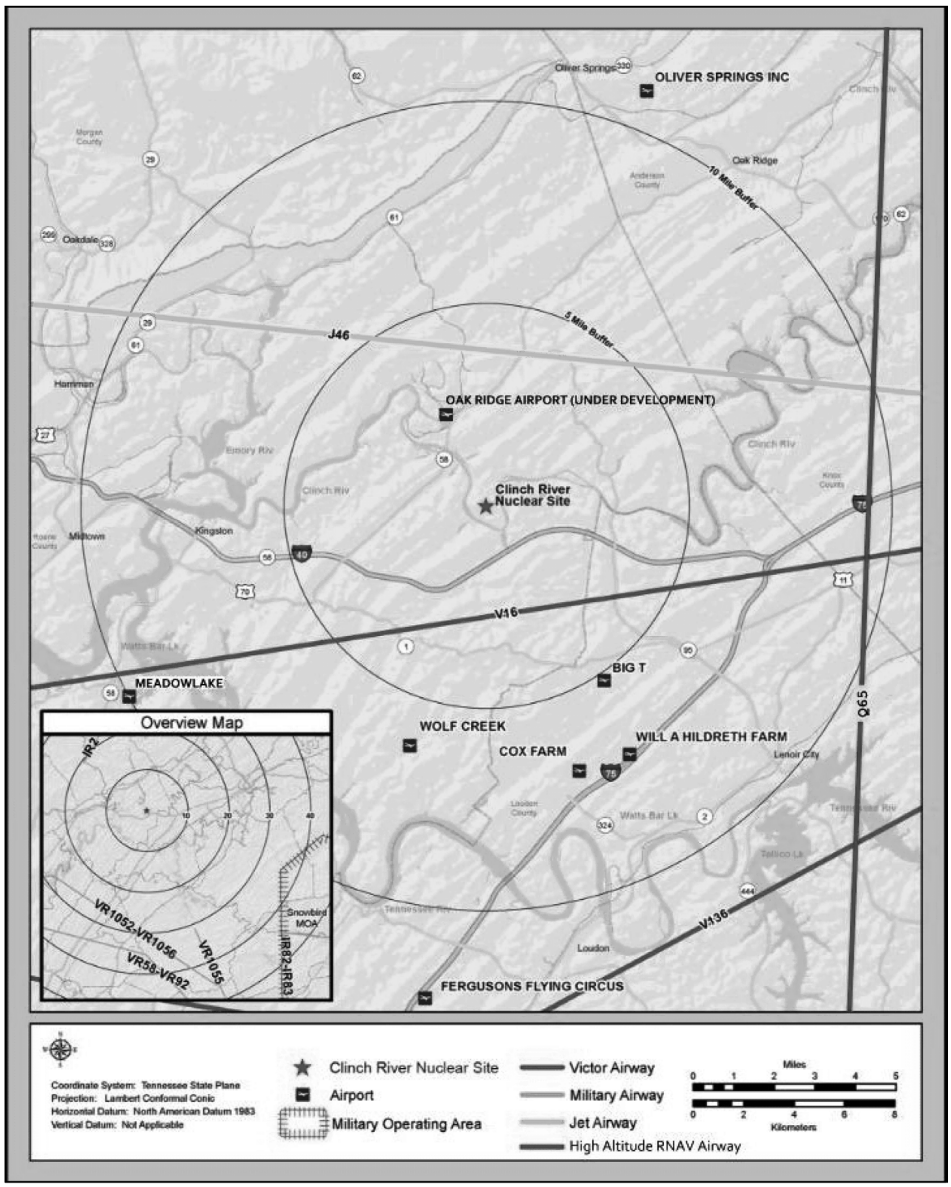

Figure 2.2-3R Location of Airports and Airways

2.3 Meteorology

Section 2.3 of the referenced ESPA SSAR is incorporated by reference with the following supplements.

2.3.1 Regional Climatology

2.3.1.1 General Climate

Replace from the fourth sentence of the second paragraph to the end of the fourth paragraph with the following:

Wind speeds are low, with a mean annual wind speed of 2.7 miles per hour (mph) at Oak Ridge (Reference 2.3.1-1). During winter when the jet stream moves southward, the Cumberland Mountains also serve to retard or moderate cold outbreaks by blocking dense, cold polar continental air masses. In summer, the topography in the region may enhance thunderstorm activity due to orographic lift (References 2.3.1-1 and 2.3.1-2).

Area temperatures measured in Oak Ridge indicate warm summers and mild winters. In January, the normal daily maximum temperature is 48.1°F with a normal daily minimum temperature 30.0°F based on 30 years of data. In July, the normal daily maximum temperature is 89.1°F, while the normal daily minimum temperature is 69.0°F based on 30 years of data (Reference 2.3.1-1). Relative humidity in the region averaged 73 percent based on a 30-year period of record from the Knoxville LCD (Reference 2.3.1-2).

Precipitation averages about 56 inches (in.) annually (Reference 2.3.1-1). Late winter (January– March) is usually the wettest season, with more than 15 in., while late summer-early autumn (August–October) is the driest season, with less than 11 in. Droughts are uncommon in this region of the United States.

Replace Reference 2.3.1-27 with Reference 2.3.1-4 in the last paragraph in ESPA SSAR Section 2.3.1.1.

2.3.1.3 Severe Weather

Replace the third sentence of the first paragraph in ESPA SSAR Section 2.3.1.3 with the following:

Most data are taken from the National Climatological Data Center (NCDC) Storm Events Database (Reference 2.3.1-4) that covers the 74-year period of 1950–2023, but even longer data periods are used for some phenomena to try to capture the occurrence of rare events.

2.3.1.3.1 Thunderstorms, Hail and Lightning

Replace ESPA SSAR Section 2.3.1.3.1 with the following:

Thunderstorms

Thunderstorms are common in the region based on a 30-year period of record (1991–2020) range of 43 days with thunderstorms at Tri-Cities to 57 days with thunderstorms at Chattanooga (References 2.3.1-2, 2.3.1-5, 2.3.1-6, 2.3.1-7 and 2.3.1-39). The greatest frequency of thunderstorms is during the summer with a range of 31-36 days during May–August. This is characteristic of a diurnal afternoon thunderstorm pattern due to solar heating.

Hail

In Roane County, hail events were reported 36 days from 1950 through December 31, 2022, or approximately 0.50 days per year, (Reference 2.3.1-4). Hail was also reported in adjacent Loudon and Knox counties 50 and 94 times, or 0.69 and 1.29 days per year, respectively, during this time period (Reference 2.3.1-4).

Lightning

The CRN Site averages 13 cloud-to-ground lightning flashes per square mile (2.6 km^2) annually (Reference 2.3.1-9).

2.3.1.3.2 Extreme Winds

Replace the second paragraph in ESPA SSAR Section 2.3.1.3.2 with the following:

Estimated extreme winds are based on climatological data from Oak Ridge and Knoxville, Tennessee (References 2.3.1-1,2.3.1-2, 2.3.1-8, 2.3.1-10, 2.3.1-11, 2.3.1-12, and 2.3.1-13) and hourly observations from TVA Sequoyah and Watts Bar Nuclear Plants (References 2.3.1-14 and 2.3.1-15).

Replace Table 2.3.1-1 with Table 2.3.1-1R in the third paragraph in ESPA SSAR Section 2.3.1.3.2.

Replace Reference 2.3.1-3 with Reference 2.3.1-10 in the fourth paragraph in ESPA SSAR Section 2.3.1.3.2.

Replace Reference 2.3.1-30 with Reference 2.3.1-16 in the fifth paragraph in ESPA SSAR Section 2.3.1.3.2.

Replace the sixth paragraph in ESPA SSAR Section 2.3.1.3.2 with the following:

For comparison, hourly average (scalar) wind speeds at the nominal 33-foot level are available from the CRN Site during 2011–2013, the Watts Bar Nuclear Plant (30 miles southwest from the CRN Site) during 1973–2018, and the Sequoyah Nuclear Plant during 1971–2018. The

maximum hourly average wind speed values of 15.1 mph for CRN Site, 30 mph for Watts Bar Nuclear Plant, and 29.8 mph for Sequoyah Nuclear Plant correspond to 3-second gust wind speeds of 23 mph, 45 mph, and 45 mph, respectively.

Replace Reference 2.3.1-15 with Reference 2.3.1-17 in the seventh paragraph in ESPA SSAR Section 2.3.1.3.2.

2.3.1.3.3 Precipitation Extremes

Replace the first sentence of the first paragraph in ESPA SSAR Section 2.3.1.3.3 with the following:

Historical precipitation for the CRN Site meteorological vicinity obtained from several surrounding National Weather Service (NWS) and TVA sites (References 2.3.1-1, 2.3.1-2, 2.3.1-5, 2.3.1-6, 2.3.1-7, 2.3.1-14 and 2.3.1-15) is summarized in Table 2.3.1-2R.

Replace Reference 2.3.1-34 with Reference 2.3.1-18 in last sentence of the first paragraph in ESPA SSAR Section 2.3.1.3.3.

Replace the first sentence of the second paragraph in ESPA SSAR Section 2.3.1.3.3 with the following:

The maximum estimated annual precipitation is in the range of 46–55 in.

Replace Table 2.3.1-2 with Table 2.3.1-2R in the second sentence of the second paragraph in ESPA SSAR Section 2.3.1.3.3.

Replace Reference 2.3.1-36 with Reference 2.3.1-19 in the third sentence of the second paragraph in ESPA SSAR Section 2.3.1.3.3.

Replace Reference 2.3.1-36 with Reference 2.3.1-19 in the fourth sentence of the second paragraph in ESPA SSAR Section 2.3.1.3.3.

2.3.1.3.4 Tornadoes

Replace the first paragraph in ESPA SSAR Section 2.3.1.3.4 with the following:

The probability of a tornado occurring at the CRN Site is low based on records from the NWS Morristown Tornado Database (Reference 2.3.1-21) and the NCDC Storm Events Database (Reference 2.3.1-4). During the 72-year period 1950-2022, six tornadoes were reported within 10 miles of the CRN Site (Table 2.3.1-3R). Only one of these had an intensity greater than F0/EF0.

Replace Reference 2.3.1-15 with Reference 2.3.1-17 in the third paragraph in ESPA SSAR Section 2.3.1.3.4.

Replace Reference 2.3.1-17 with Reference 2.3.1-22 in the parameter definition section of Equation 2.3.1-1 in ESPA SSAR Section 2.3.1.3.4.

2.3.1.3.5 Hurricanes

Replace the third paragraph in ESPA SSAR Section 2.3.1.3.5 with the following:

Review of the NCDC Storm Events Database for the period of January 1, 1950, through December 31, 2022, shows that there was only one tropical storm on September 16, 2004, near Roane County that caused minimal damage. This storm was associated with Hurricane Ivan.

2.3.1.3.6 Winter Storm Events

Replace Reference 2.3.1-5 with Reference 2.3.1-2 in the first sentence of the first paragraph in ESPA SSAR Section 2.3.1.3.6.

Replace Table 2.3.1-2 with Table 2.3.1-2R in the second sentence of the first paragraph in ESPA SSAR Section 2.3.1.3.6.

Replace Reference 2.3.1-2 with Reference 2.3.1-5 in the second sentence of the first paragraph in ESPA SSAR Section 2.3.1.3.6.

Replace Reference 2.3.1-18 with Reference 2.3.1-23 at the end of the second paragraph in ESPA SSAR Section 2.3.1.3.6.

2.3.1.3.6.1 Ice Storms

Replace Reference 2.3.1-19 with Reference 2.3.1-24 in first paragraph in ESPA SSAR Section 2.3.1.3.6.1.

Replace Reference 2.3.1-30 with Reference 2.3.1-16 in the third paragraph in ESPA SSAR Section 2.3.1.3.6.1.

2.3.1.3.6.2 Normal and Extreme Winter Precipitation Events

Replace the third paragraph in ESPA SSAR Section 2.3.1.3.6.2 with the following:

The maximum reported snow depth at Chattanooga, TN (Reference 2.3.1-5), the highest snow depth at a nearby NWS station, was used to estimate the weight of the maximum historic snowpack at the CRN Site. The greatest snow depth reported during the 84-year period of record (1938–2022) for Chattanooga, was 20 in. in March 1993. Interim Staff Guidance (ISG) on Assessment of Normal and Extreme Winter Precipitation Loads on the Roofs of Seismic Category I Structures (ISG-7) (Reference 2.3.1-25), provides an algorithm (below) for converting historical maximum snowpack depth to a ground snow load.

Replace the fourth paragraph in ESPA SSAR Section 2.3.1.3.6.2 with the following:

Using the 20-inch snow depth for Chattanooga gives a snow load of 16.4 psf for the maximum historical snowpack.

Replace Reference 2.3.1-39 with Reference 2.3.1-26 in the fifth paragraph in ESPA SSAR Section 2.3.1.3.6.2.

Replace Reference 2.3.1-32 with Reference 2.3.1-27 in the eighth paragraph in ESPA SSAR Section 2.3.1.3.6.2.

2.3.1.4 Design Basis Dry- and Wet-Bulb Temperatures

Replace Reference 2.3.1-33 with Reference 2.3.1-28 in the second paragraph in ESPA SSAR Section 2.3.1.4.

2.3.1.5 Meteorological Data for Evaluating Ultimate Heat Sink

Replace the first sentence of the first paragraph in ESPA SSAR Section 2.3.1.5 with the following:

The GEH BWRX-300 design being evaluated does not rely on an external water source as its ultimate heat sink.

2.3.1.6 Climate Changes

Replace the first paragraph in ESPA SSAR Section 2.3.1.6 with the following:

While climatic conditions change over time, such changes are cyclical in nature on various time and spatial scales. The timing, magnitude, relative contributions to, and implications of these changes are generally more speculative, even for specific areas or locations. Further, the most extreme projected changes are for time scales much longer than any facility will be operated at CRN. Projected changes are generally small compared to natural variation. General predictions of global or U.S. climatic changes expected during the period of reactor operation are uncertain and are only applicable on a macroclimatic scale. Since the maximum data span available was used in the severe weather analysis, accurate severe weather phenomena have been provided based on best-available historic data. Projections of future severe weather conditions at the CRN Site are highly uncertain at best, based on current understanding and modeling of global climate change. Predictions provided by the USGS (Reference 2.3.1-29) vary considerably, yet 100% of models agree on temperature increasing. For example, the Community Climate System Model, version 4 (CCSM4) model gives a summer maximum temperature increase from approximately 88ºF to 95ºF with a standard deviation of approximately 3ºF over the period of 2025 through 2075. The HadGEM2-ES365 model gives a summer maximum temperature increase from approximately 88ºF to 101ºF with a standard deviation of approximately 4ºF over the period of 2025 through 2075. TVA’s major planning processes, consistent with its Climate

Change Adaptation Plan, identify opportunities as well as climate change risks with the potential to substantially impair, obstruct or prevent the success of Agency mission activities, both in the near term and particularly in the long term, using the best available science and information.

Replace Table 2.3.1-4 with Table 2.3.1-4R in the second paragraph in ESPA SSAR Section 2.3.1.6.

Replace the last sentence of the second paragraph in ESPA SSAR Section 2.3.1.6 with the following:

Based on the consistency of these records over the period of 1921 to 2020, significant climate changes are not expected during the licensing period.

2.3.1.7.1 Background Air Quality

Replace the last sentence of the second paragraph in ESPA SSAR Section 2.3.1.7.1 with the following:

Ambient air quality measurements in the vicinity of the CRN Site in 2013 and 2022 are shown in Table 2.3.1-5R (Reference 2.3.1-32). As of 2017, all neighboring counties have been redesignated to maintenance (Table 2.3.1-6).

Replace References 2.3.1-22 through 2.3.1-25 with References 2.3.1-32 through 2.3.1-35 in the first sentence of the second paragraph in ESPA SSAR Section 2.3.1.7.1.

Replace Reference 2.3.1-23 with Reference 2.3.1-33 in the second sentence of the second paragraph in ESPA SSAR Section 2.3.1.7.1.

Replace Reference 2.3.1-24 with Reference 2.3.1-34 in the third sentence of the second paragraph in ESPA SSAR Section 2.3.1.7.1.

Replace Reference 2.3.1-25 with Reference 2.3.1-35 in the first sentence of the fourth paragraph in ESPA SSAR Section 2.3.1.7.1.

Replace Reference 2.3.1-22 with Reference 2.3.1-32 in the second sentence of the fourth paragraph in ESPA SSAR Section 2.3.1.7.1.

Replace References 2.3.1-35 with Reference 2.3.1-36 in the second sentence of the fourth paragraph in ESPA SSAR Section 2.3.1.7.1.

Replace Reference 2.3.1-26 with Reference 2.3.1-37 in the last sentence of the last paragraph in ESPA SSAR Section 2.3.1.7.1.

2.3.1.7.2 Projected Air Quality

Insert the following after the last sentence in ESPA SSAR Section 2.3.1.7.2:

If there is construction of an air contaminant source on the CRN site, a Non-Title V Construction Permit and then Non-Title V Operating Permit will be required from the Tennessee Division of Air Pollution Control.

2.3.1.8 References

Replace ESPA SSAR Section 2.3.1.8 with the following:

2.3.2 Local Meteorology

Replace the first sentence of the third paragraph in ESPA SSAR Section 2.3.2 with the following:

The CRN Site is located at an elevation of approximately 814.5 feet above mean sea-level on a peninsula formed by the Clinch River arm of the Watts Bar Reservoir.

Replace the last sentence of the third paragraph in ESPA SSAR Section 2.3.2 with the following:

Figures 2.3.2-70 through 2.3.2-77 show the elevation profiles within 50 miles of the site in each of the compass directions.

2.3.2.1.1 Winds

Replace the third and fourth sentences of the second paragraph in ESPA SSAR Section 2.3.2.1 with the following:

Wind roses for Chattanooga, based on ten years of data (2012--2022), are presented in Figures 2.3.2-29R through 2.3.2-41R. Wind roses for Oak Ridge, based on ten years of data (2012–2022), are presented in Figures 2.3.2-42R through 2.3.2-54R and wind roses for Knoxville based on 2012-2022 are presented in Figures 2.3.2-55R through 2.3.2-67R.

Replace Figure 2.3.2-55 with Figure 2.3.2-68 in the second sentence of the fifth paragraph in ESPA SSAR Section 2.3.2.1.1.

2.3.2.1.2 Air Temperature

Replace Tables 2.3.2-5 and 2.3.2-6 with Tables 2.3.2-5R and 2.3.2-6R in ESPA SSAR Section 2.3.2.1.2.

2.3.2.1.3 Atmospheric Moisture

Replace Table 2.3.2-7 with Table 2.3.2-7R in ESPA SSAR Section 2.3.2.1.3.

2.3.2.1.4 Precipitation

Replace the second sentence of the fourth paragraph in ESPA SSAR Section 2.3.2.1.4 with the following:

This data was taken from NOAA Atlas 14 Point Precipitation Frequency Estimates Data Server (Reference 2.3.2-4) and NOAA Atlas 14 Precipitation-Frequency Atlas of the United States (Reference 2.3.2-5).

Replace Table 2.3.2-9 with Table 2.3.2-9R in ESPA SSAR Section 2.3.2.1.4.

Replace Table 2.3.2-10 with Table 2.3.2-10R in ESPA SSAR Section 2.3.2.1.4.

Replace Table 2.3.2-11 with Table 2.3.2-11R in ESPA SSAR Section 2.3.2.1.4.

Replace Table 2.3.2-16 with Table 2.3.2-16R in ESPA SSAR Section 2.3.2.1.4.

Replace Reference 2.3.2-4 with Reference 2.3.2-6 in the sixth paragraph in ESPA SSAR Section 2.3.2.1.4.

2.3.2.1.5 Fog

Replace Table 2.3.2-13 with Table 2.3.2-13R in ESPA SSAR Section 2.3.2.1.5.

2.3.2.1.6 Atmospheric Stability

Replace Reference 2.3.2-5 with Reference 2.3.2-7 in the third paragraph in ESPA SSAR Section 2.3.2.1.6.

2.3.2.2 Potential Influence of the Plant and Its Facilities on Local Meteorology

Replace Reference 2.3.2-11 with Reference 2.3.2-8 in the second paragraph in ESPA SSAR Section 2.3.2.2.

Replace Reference 2.3.2-6 with Reference 2.3.2-9 in the second paragraph in ESPA SSAR Section 2.3.2.2.

Replace Reference 2.3.2-7 with Reference 2.3.2-10 in the second paragraph in ESPA SSAR Section 2.3.2.2.

Replace the second paragraph in ESPA SSAR Section 2.3.2.2 (Addresses ESP COL Action Item 2.3-1):

The specific cooling tower design has not been determined for the CRN site. Subsequent analysis performed since the CRN ESPA has shown that the cooling tower plume characteristics meet the NUREG 1555 guidelines. The updated evaluations of cooling tower impacts using the BWRX-300 layout on the CRN Site, (assuming linear, back-to-back cell, mechanical draft cooling towers (LMDCT)), confirmed that no salt deposition rates in the highest category are expected. The nearest offsite vegetation receptor (opposite side of the river) is approximately 900 feet (274 meters). The limiting salt deposition occurs during the winter. At 200 meters, the highest deposition rate is 354.52 kg/km^2/month in the ENE direction. Therefore, no significant impact to local vegetation is expected and the assumed cooling tower is suitable for use at the CRN Site.

The minimum distance to the switchyard is approximately 1184 feet (360 meters) and the minimum distance to the transformers is approximately 721 feet (220 meters). Thus, the distance to the transformers is the limiting distance for salt deposition. The maximum salt deposition rate is in the winter with a value of 203.09 kg/km^2/month at 200 meters in the WSW direction.

Therefore, impact to the switchyard and the plant transformers from cooling tower salt deposition is expected to be minimal. Water deposition, annual salt and TDS deposition, plume shadowing, plume length frequency, and plume height frequency were also determined for the LMDCTs. Results for these parameters are illustrated in Figures 2.3.2-78R through 2.3.2-82R.

2.3.2.4 References

Replace ESPA SSAR Section 2.3.2.4 with the following:

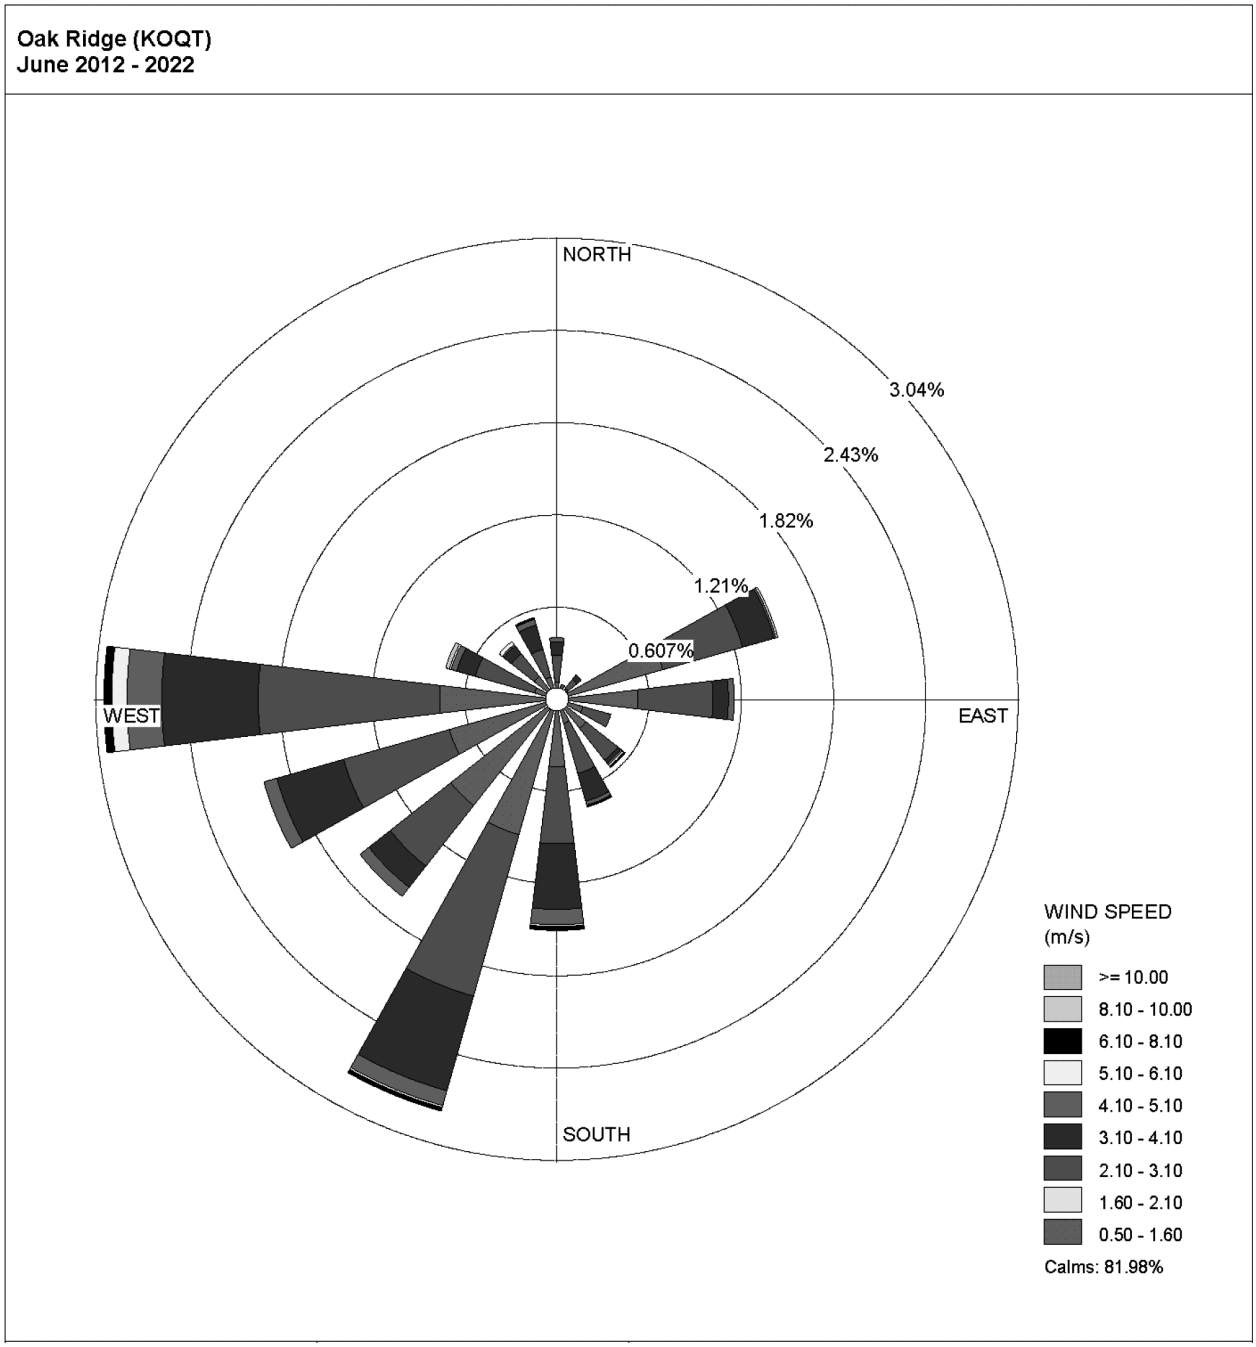

Figure 2.3.2-48R Wind Rose Oak Ridge 10 Years (2012–2022) June

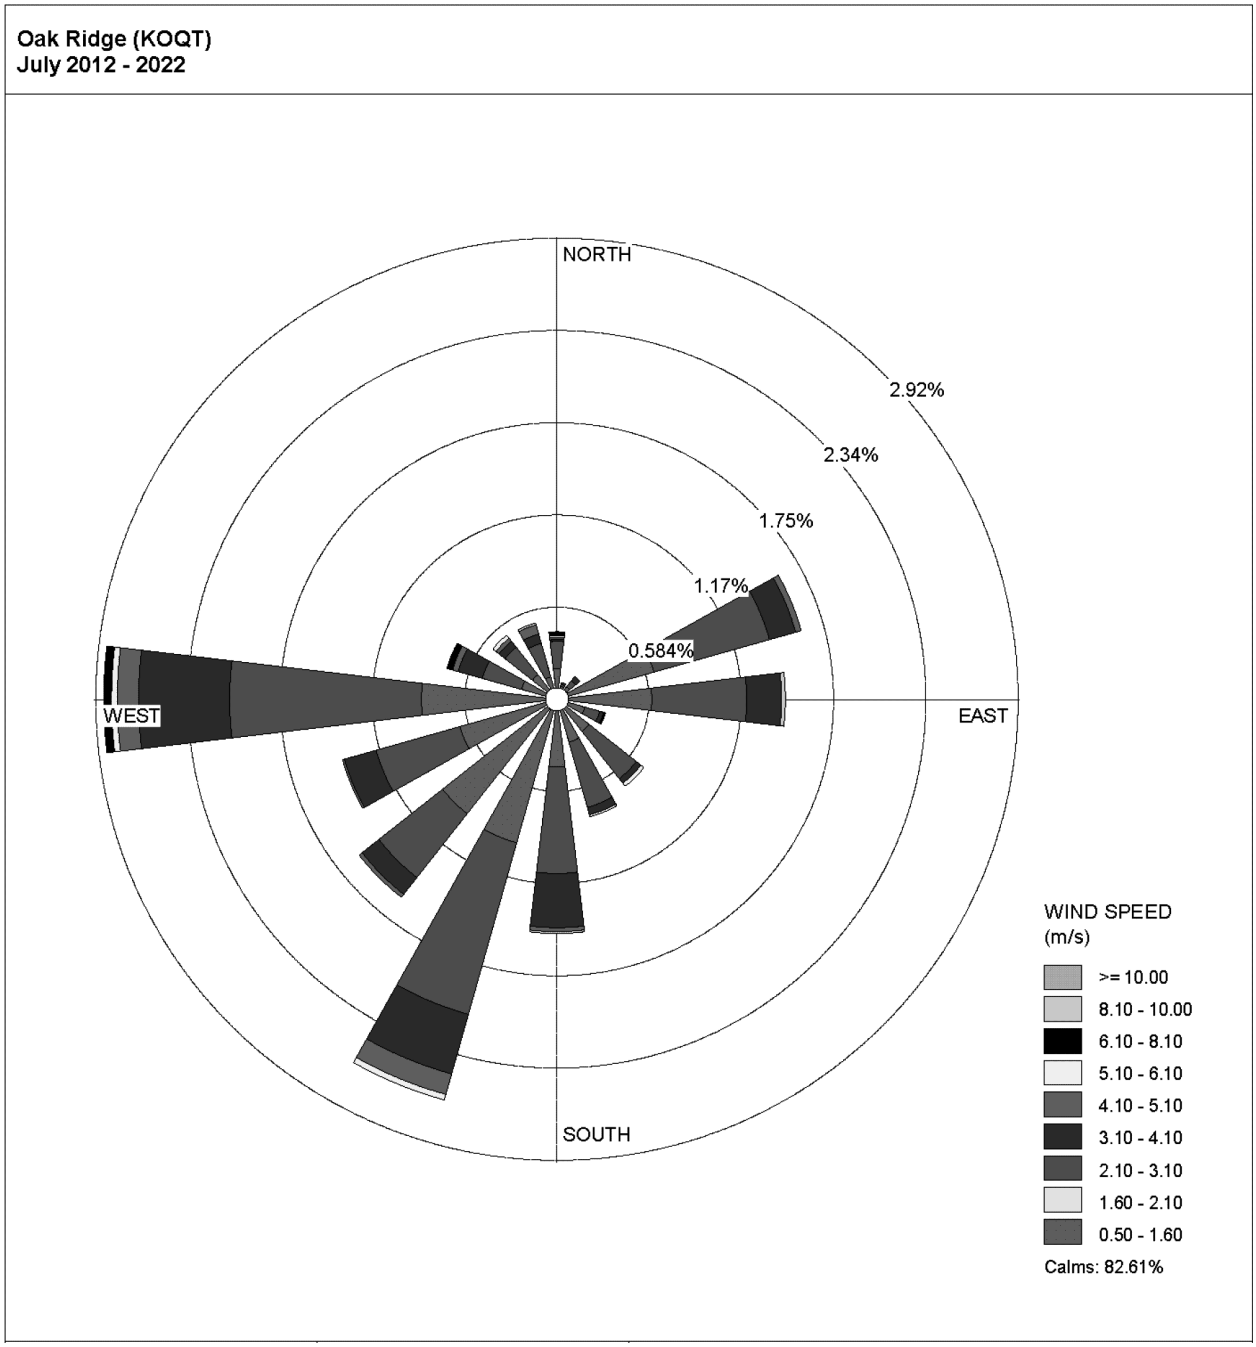

Figure 2.3.2-49R Wind Rose Oak Ridge 10 Years (2012–2022) July

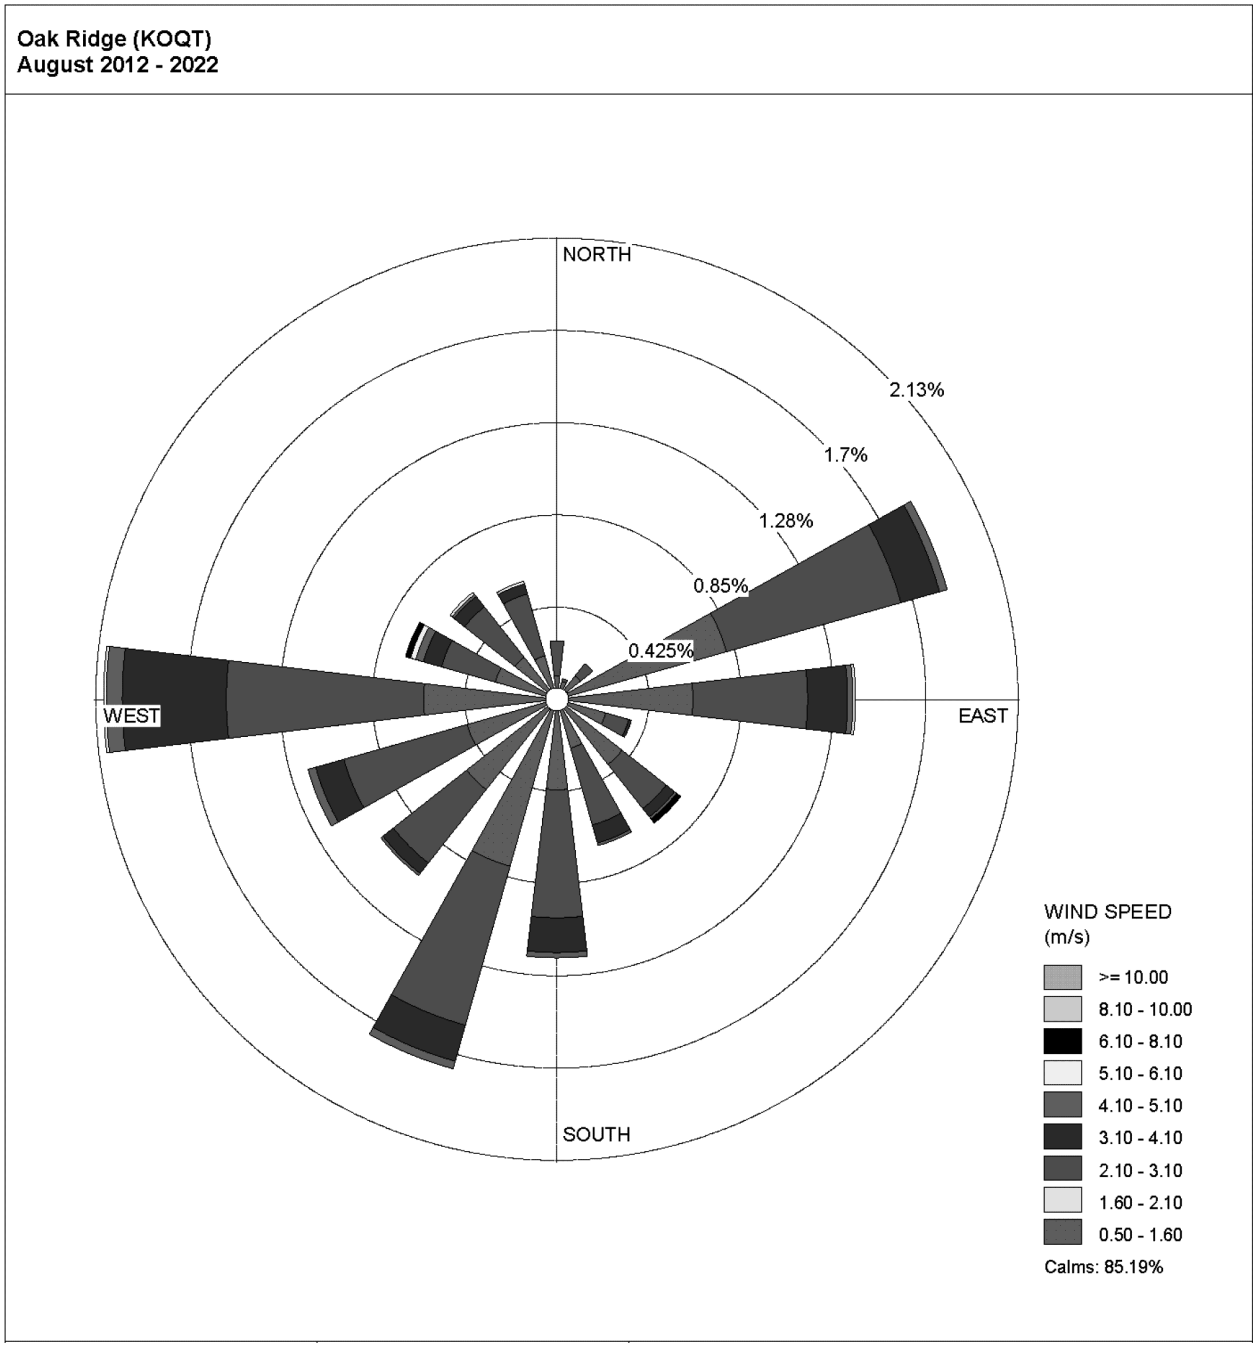

Figure 2.3.2-50R Wind Rose Oak Ridge 10 Years (2012–2022) August

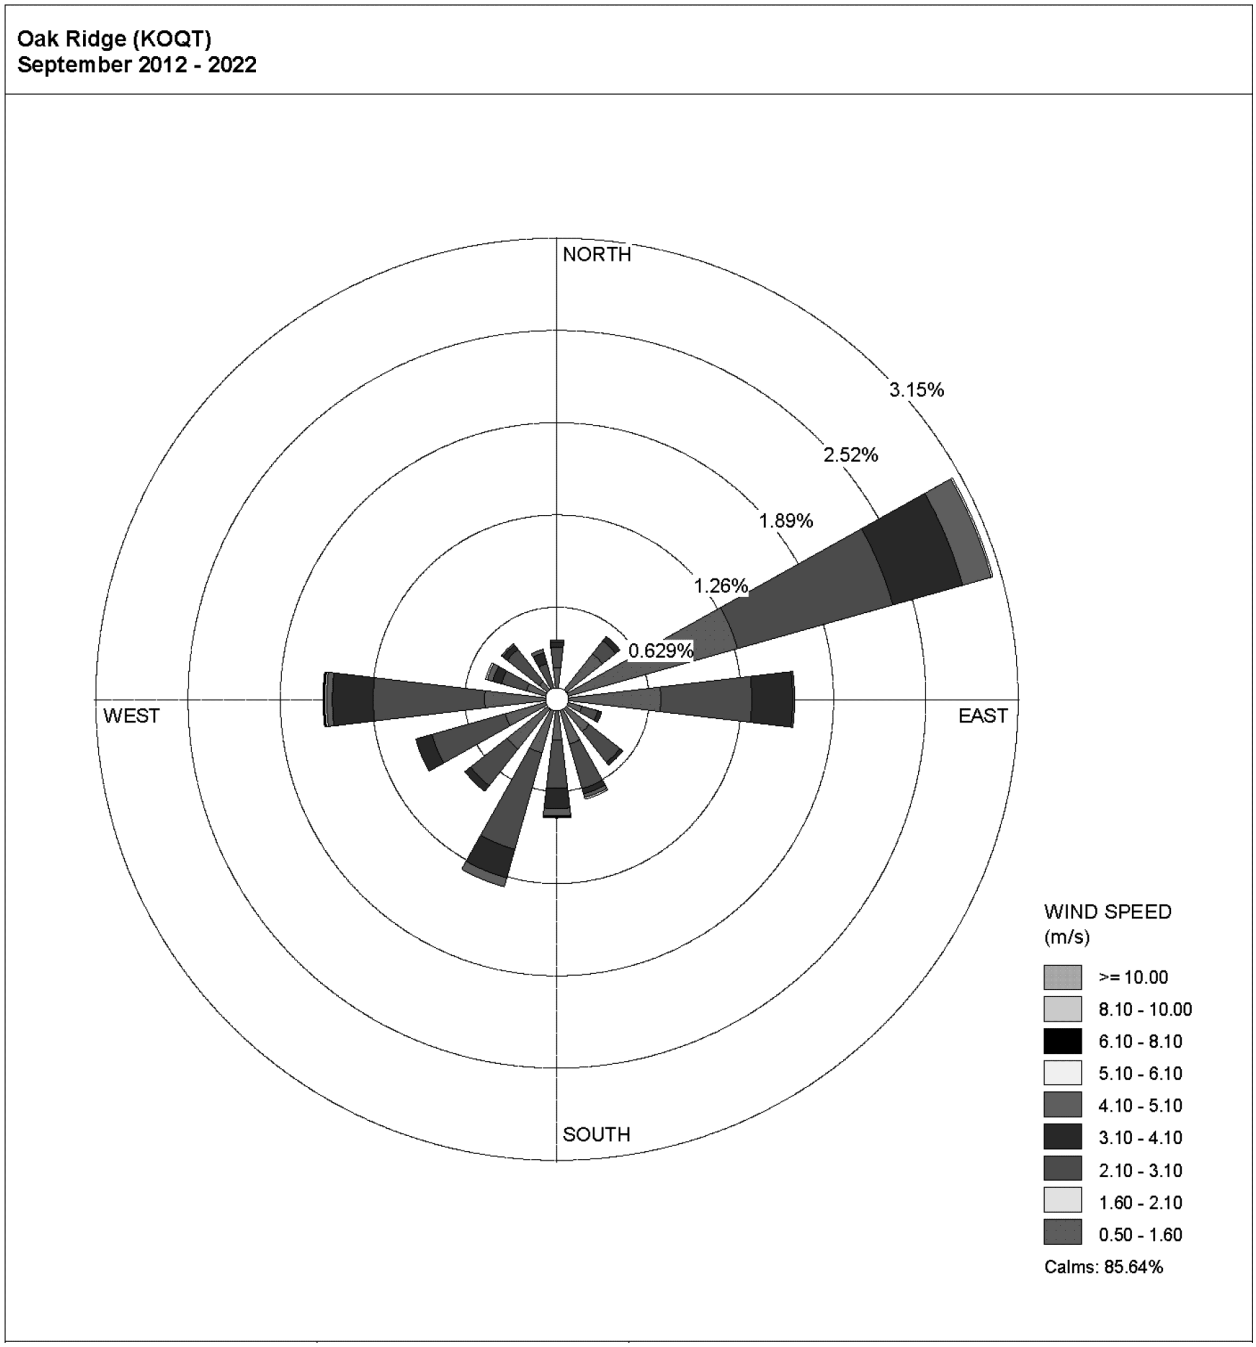

Figure 2.3.2-51R Wind Rose Oak Ridge 10 Years (2012–2022) September

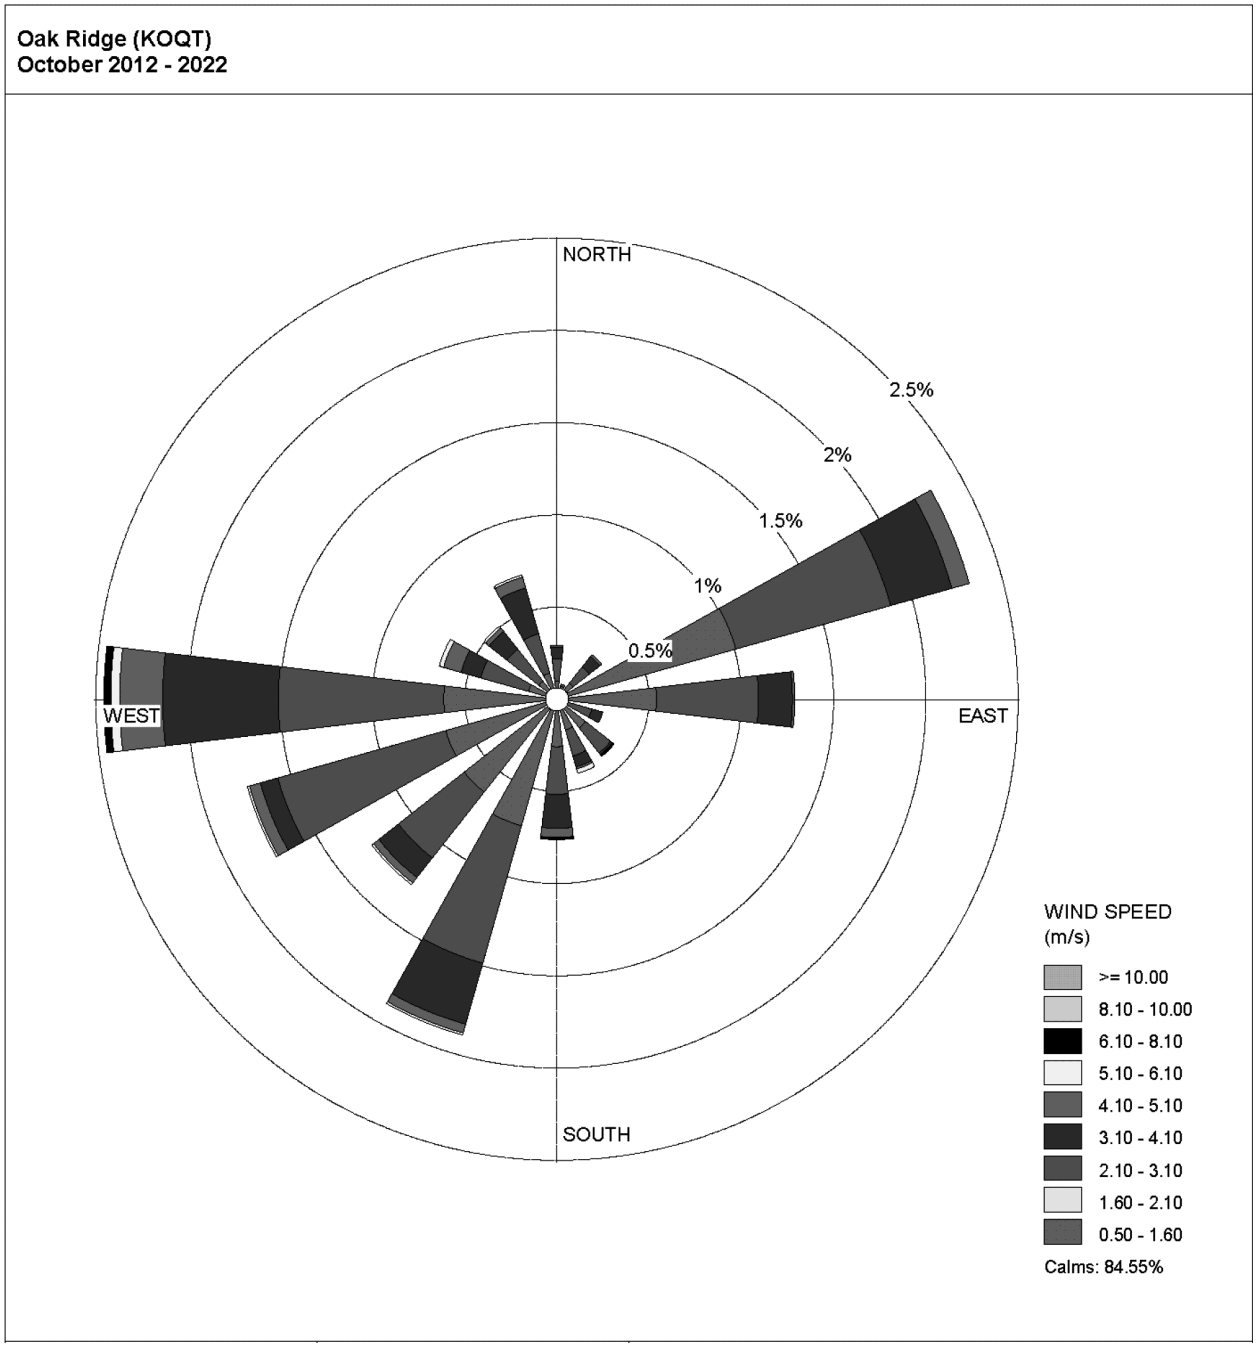

Figure 2.3.2-52R Wind Rose Oak Ridge 10 Years (2012–2022) October

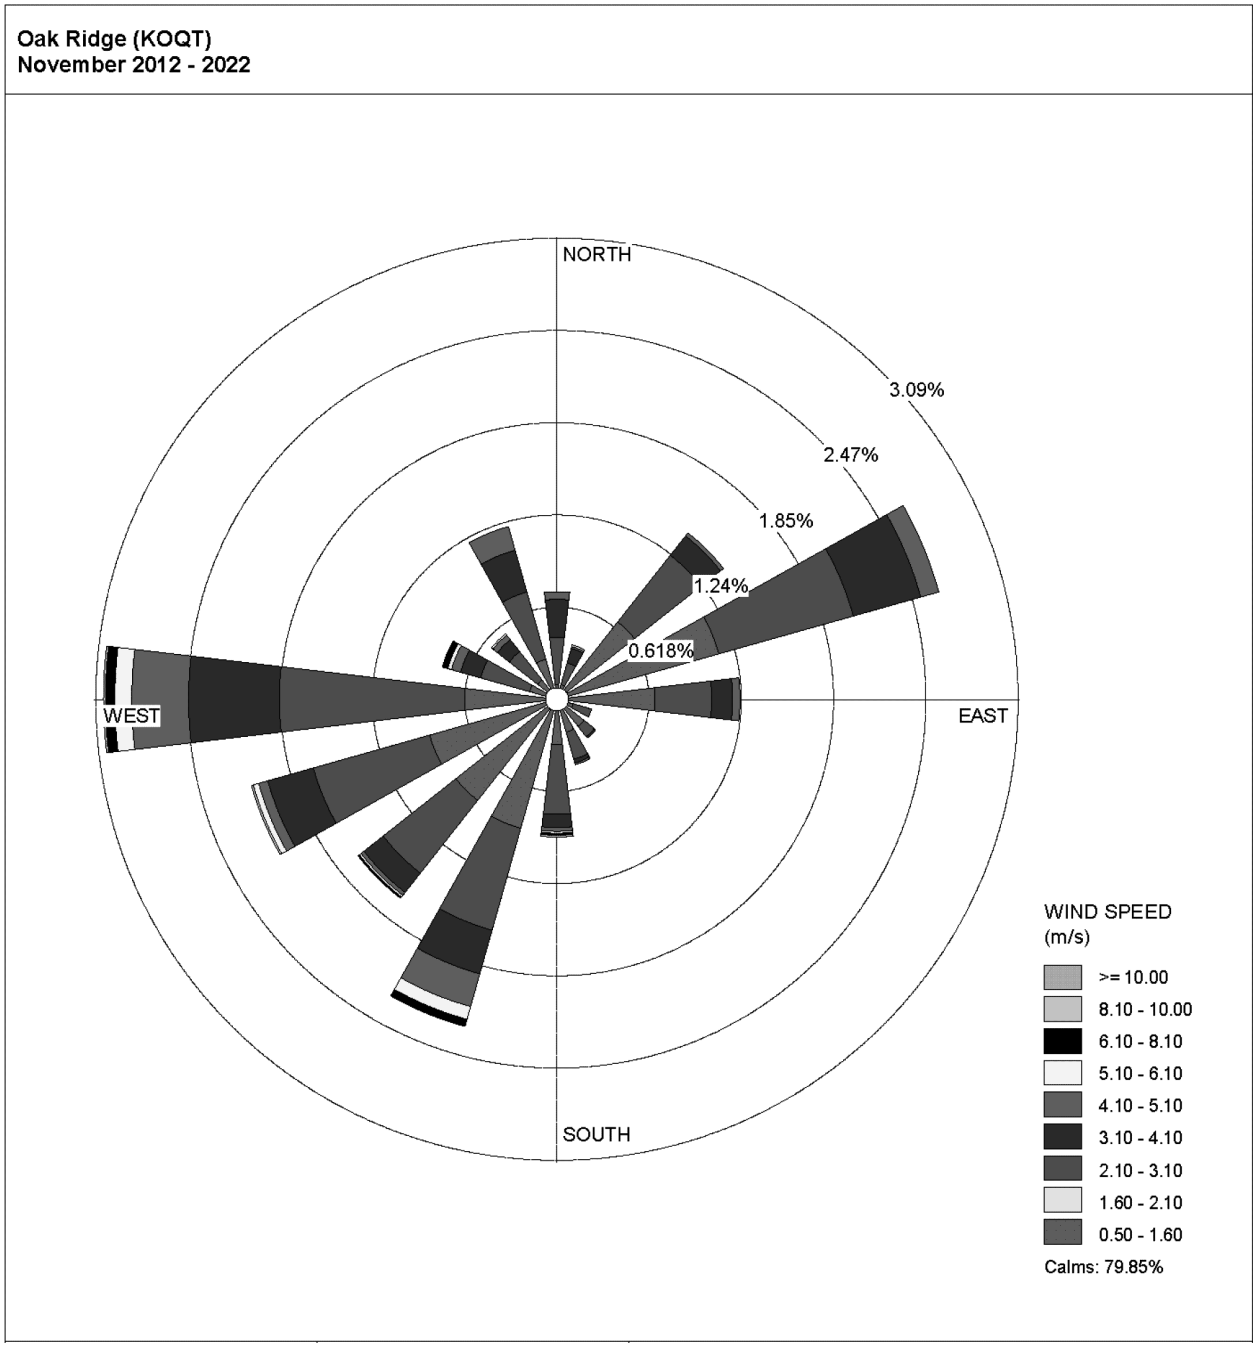

Figure 2.3.2-53R Wind Rose Oak Ridge 10 Years (2012–2022) November

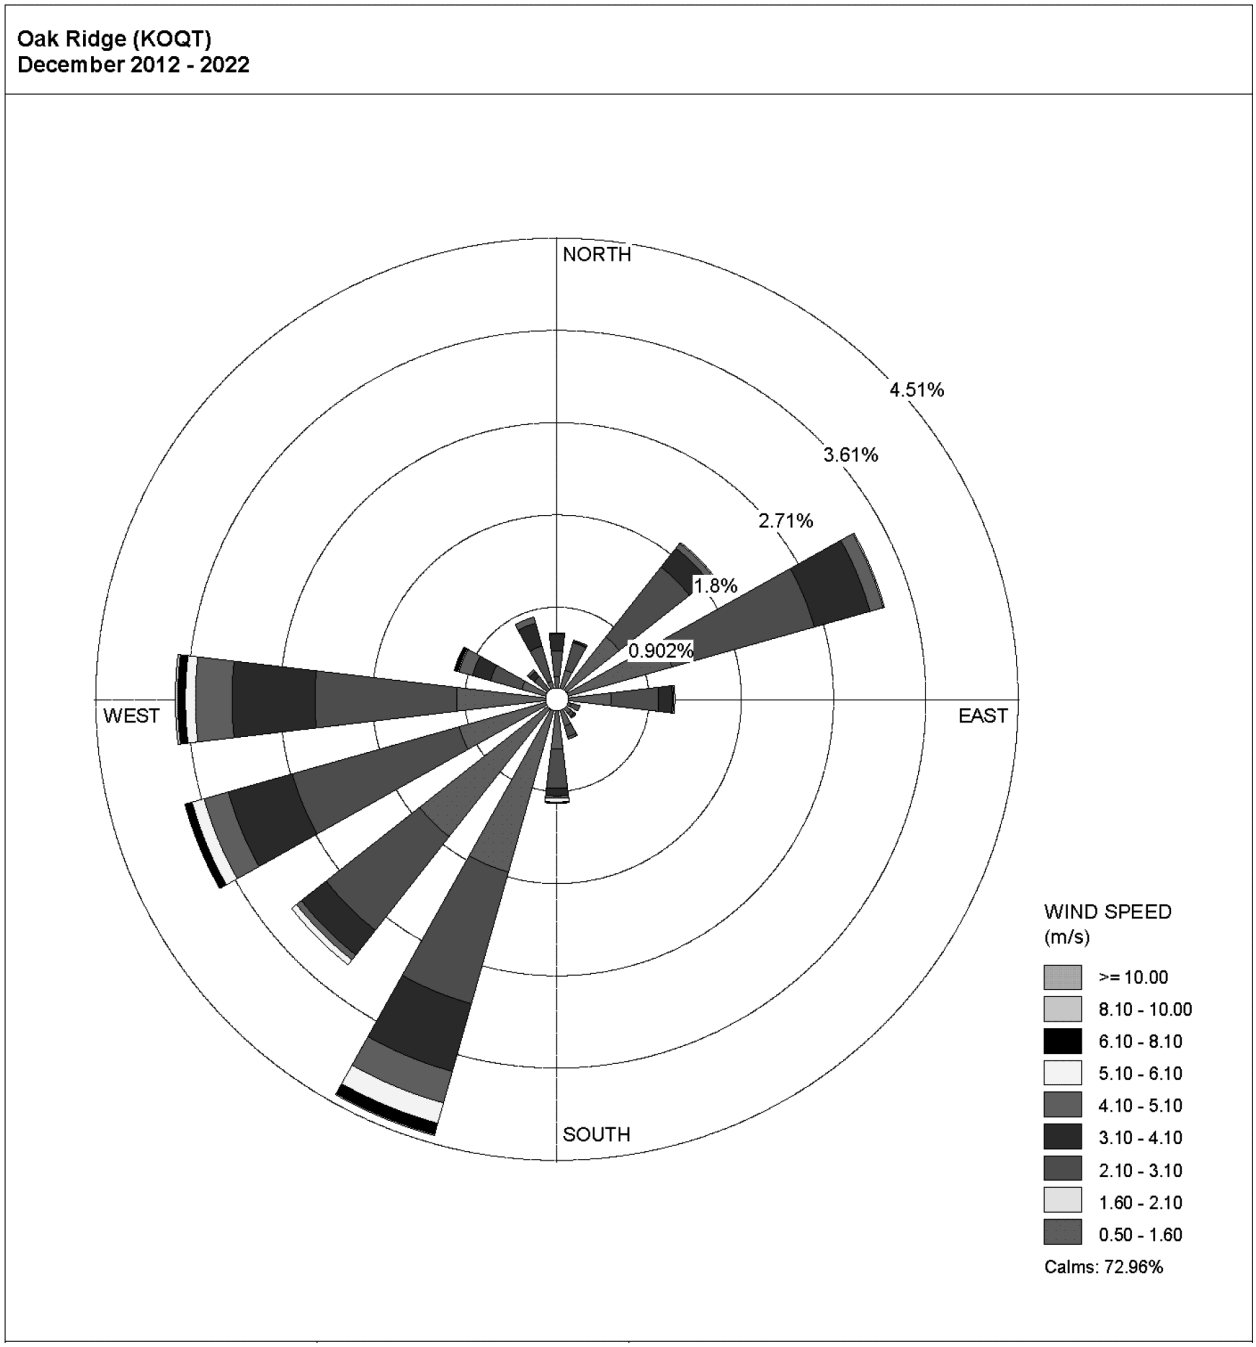

Figure 2.3.2-54R Wind Rose Oak Ridge 10 Years (2012–2022) December

Renumber ESPA SSAR Figure 2.3.2-55 through Figure 2.3.2-64 to Figure 2.3.2-68 through Figure 2.3.2-77.

Add new Figure 2.3.2-55R through Figure 2.3.2-67R with the following:

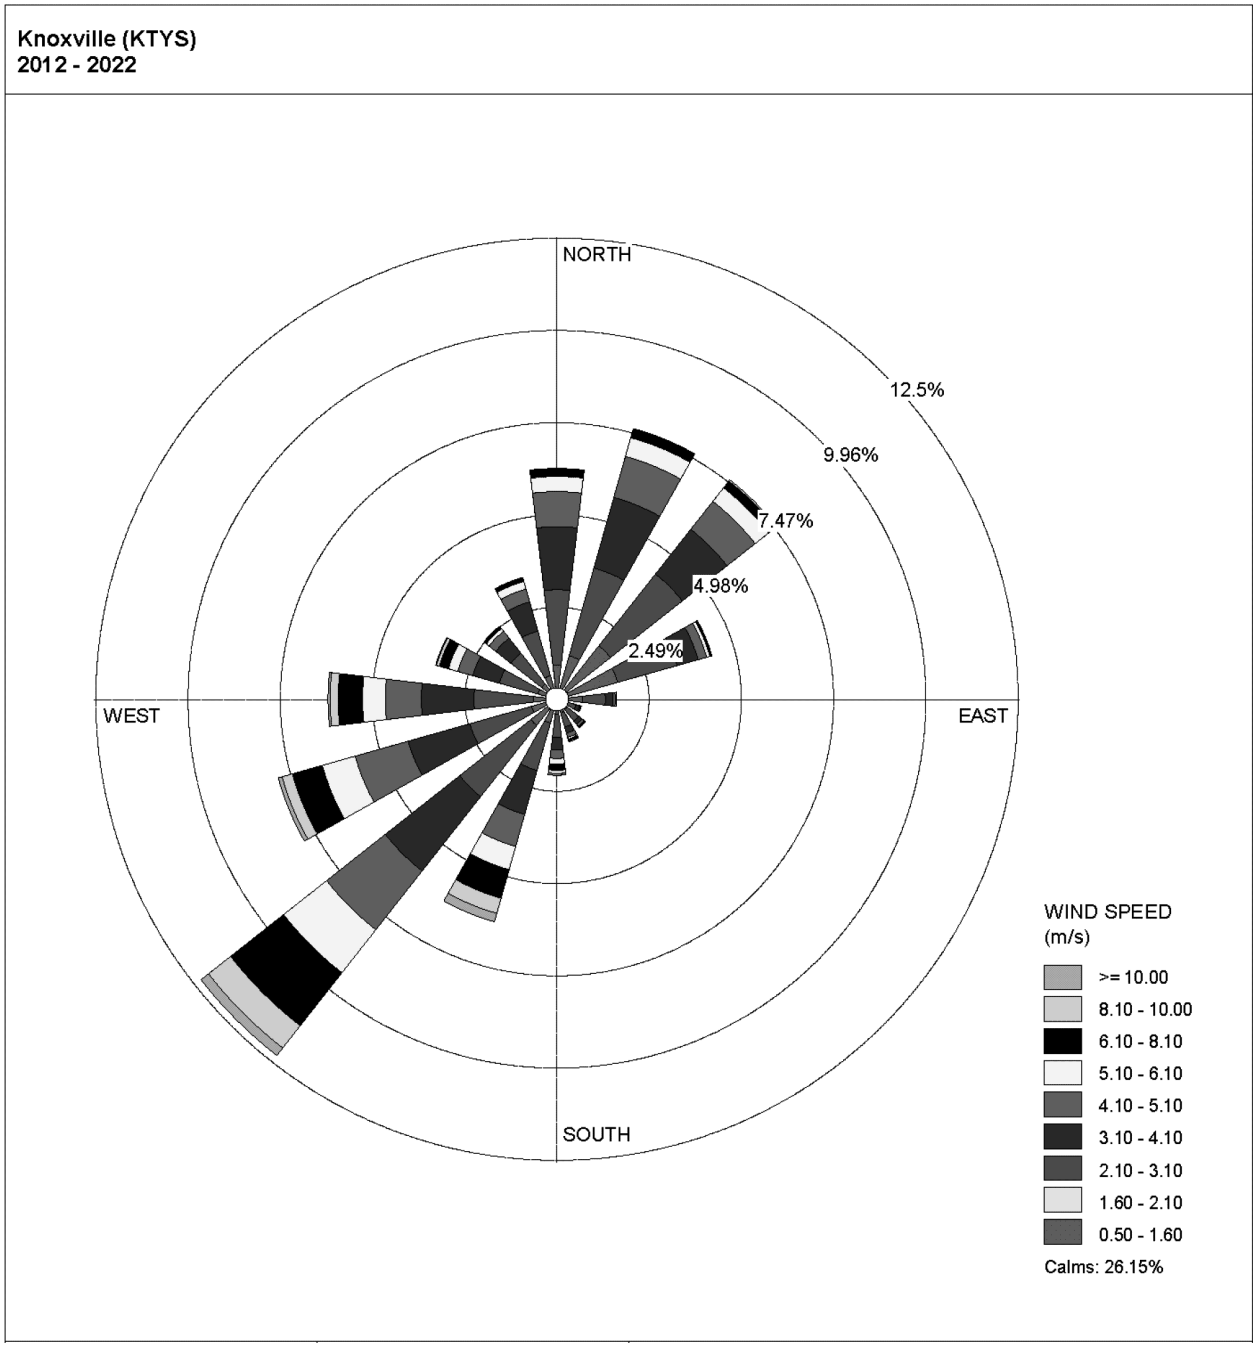

Figure 2.3.2-55R Wind Rose Knoxville 10 Years (2012–2022) All years

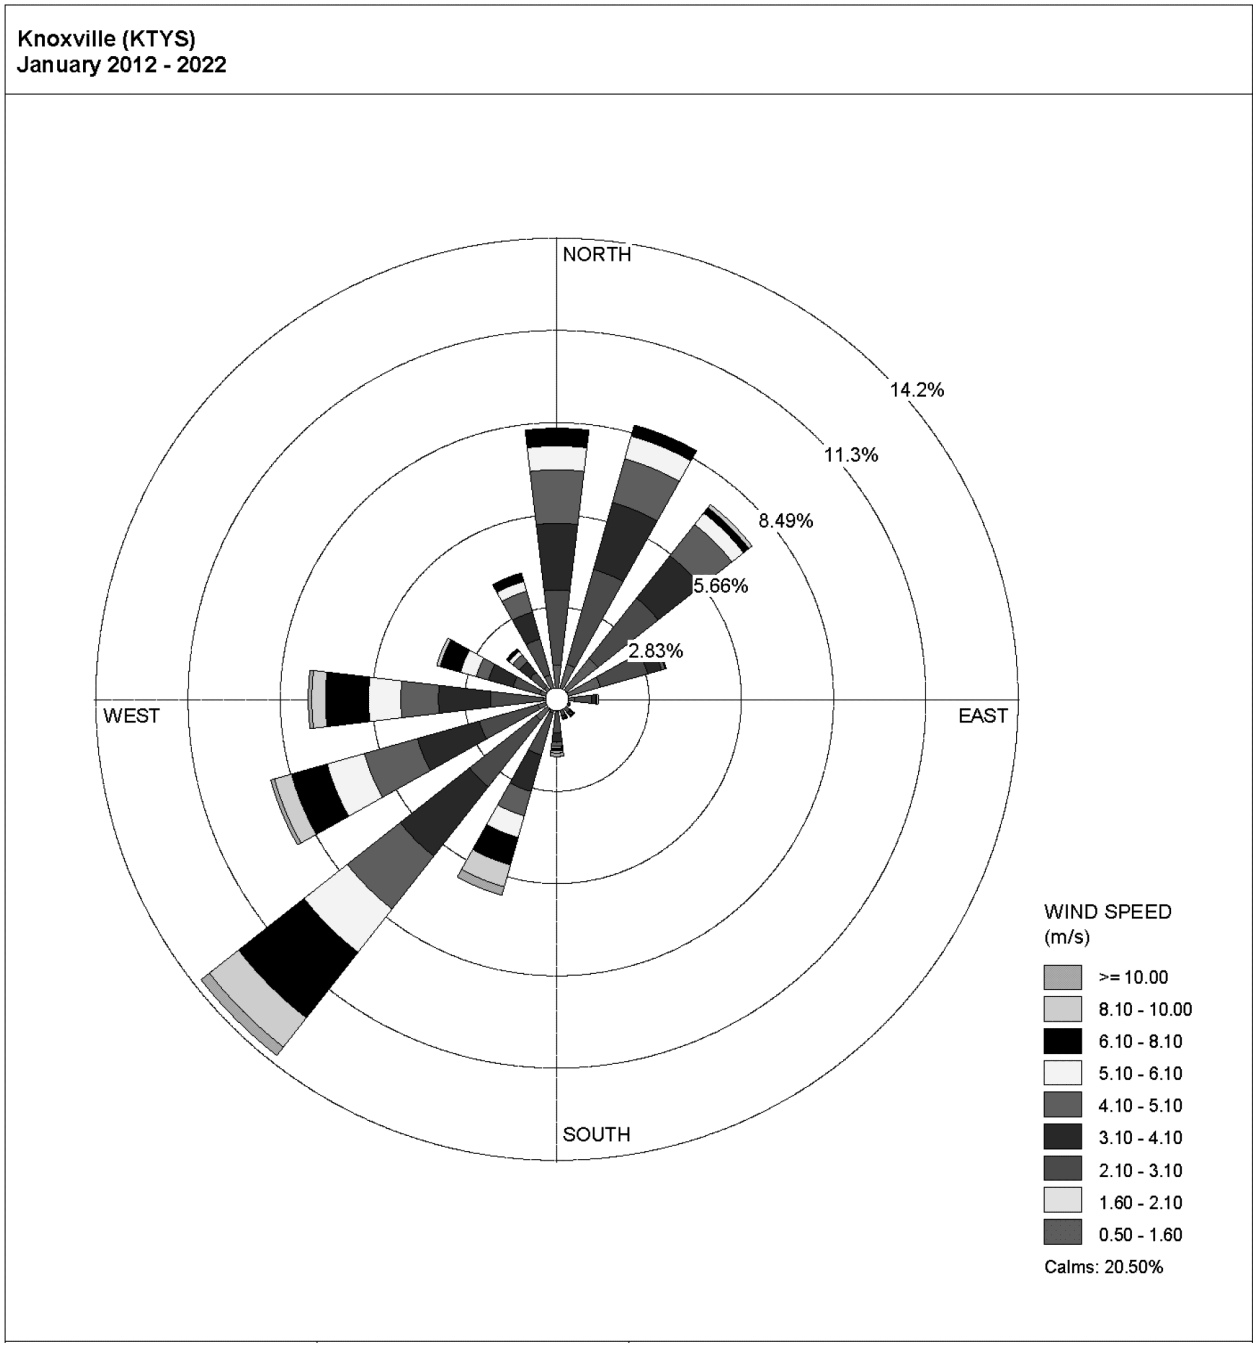

Figure 2.3.2-56R Wind Rose Knoxville 10 Years (2012–2022) January

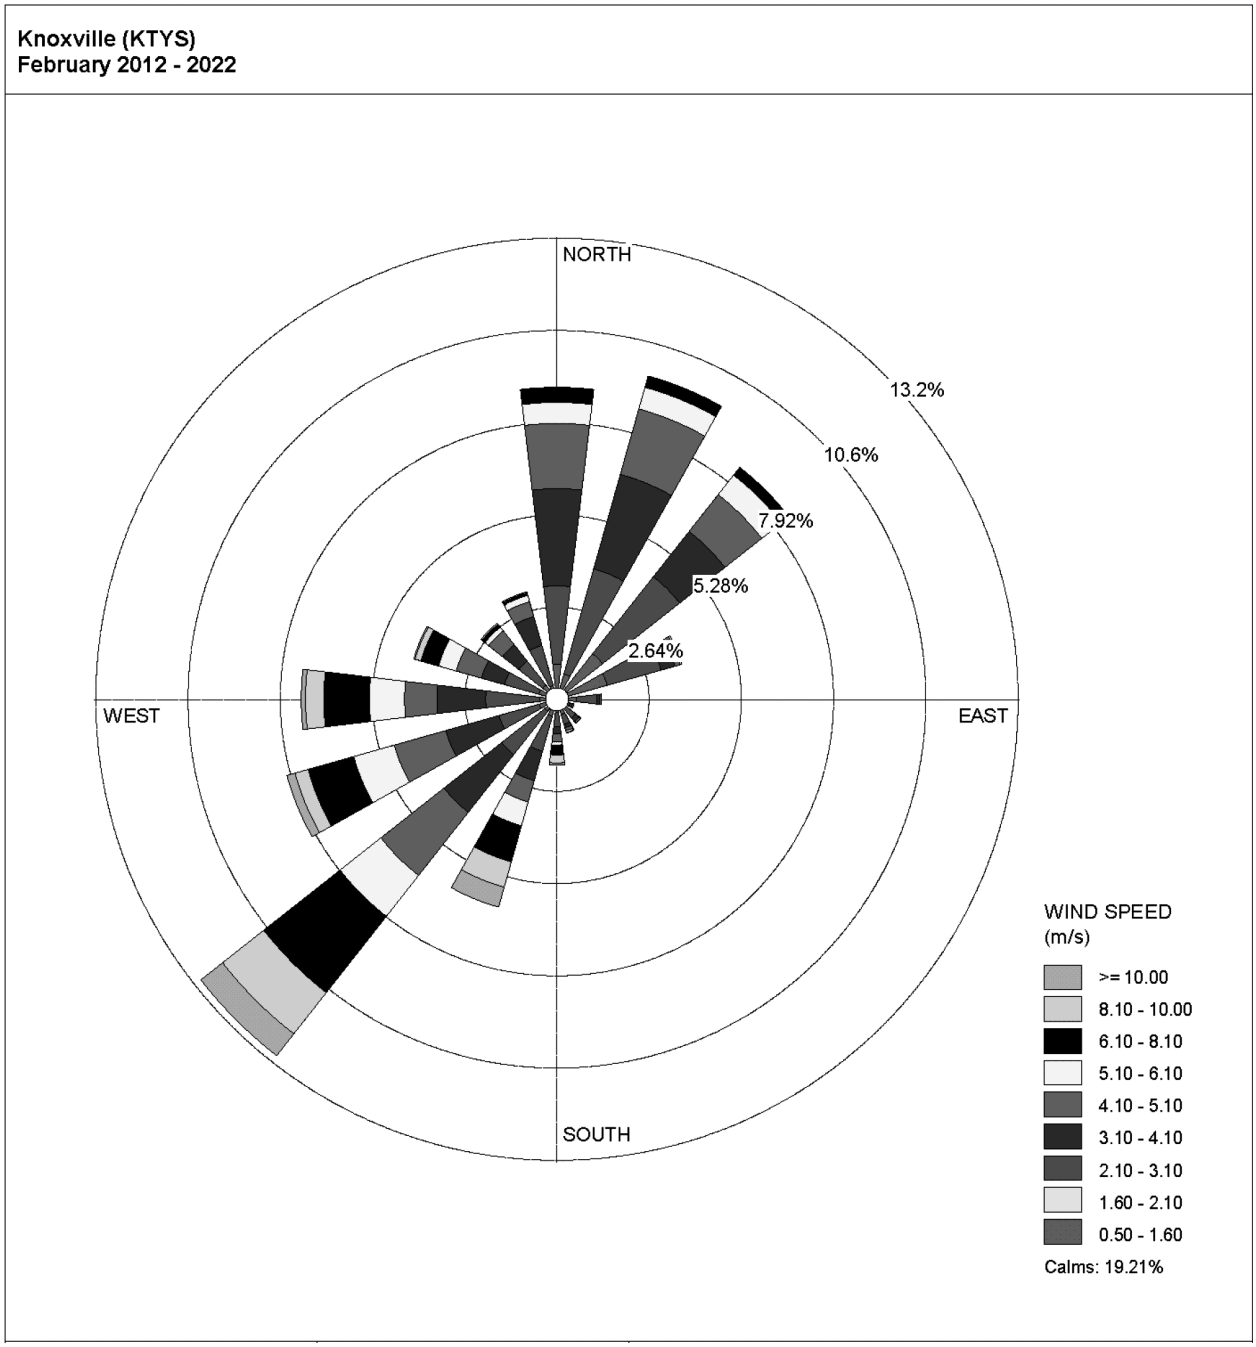

Figure 2.3.2-57R Wind Rose Knoxville 10 Years (2012–2022) February

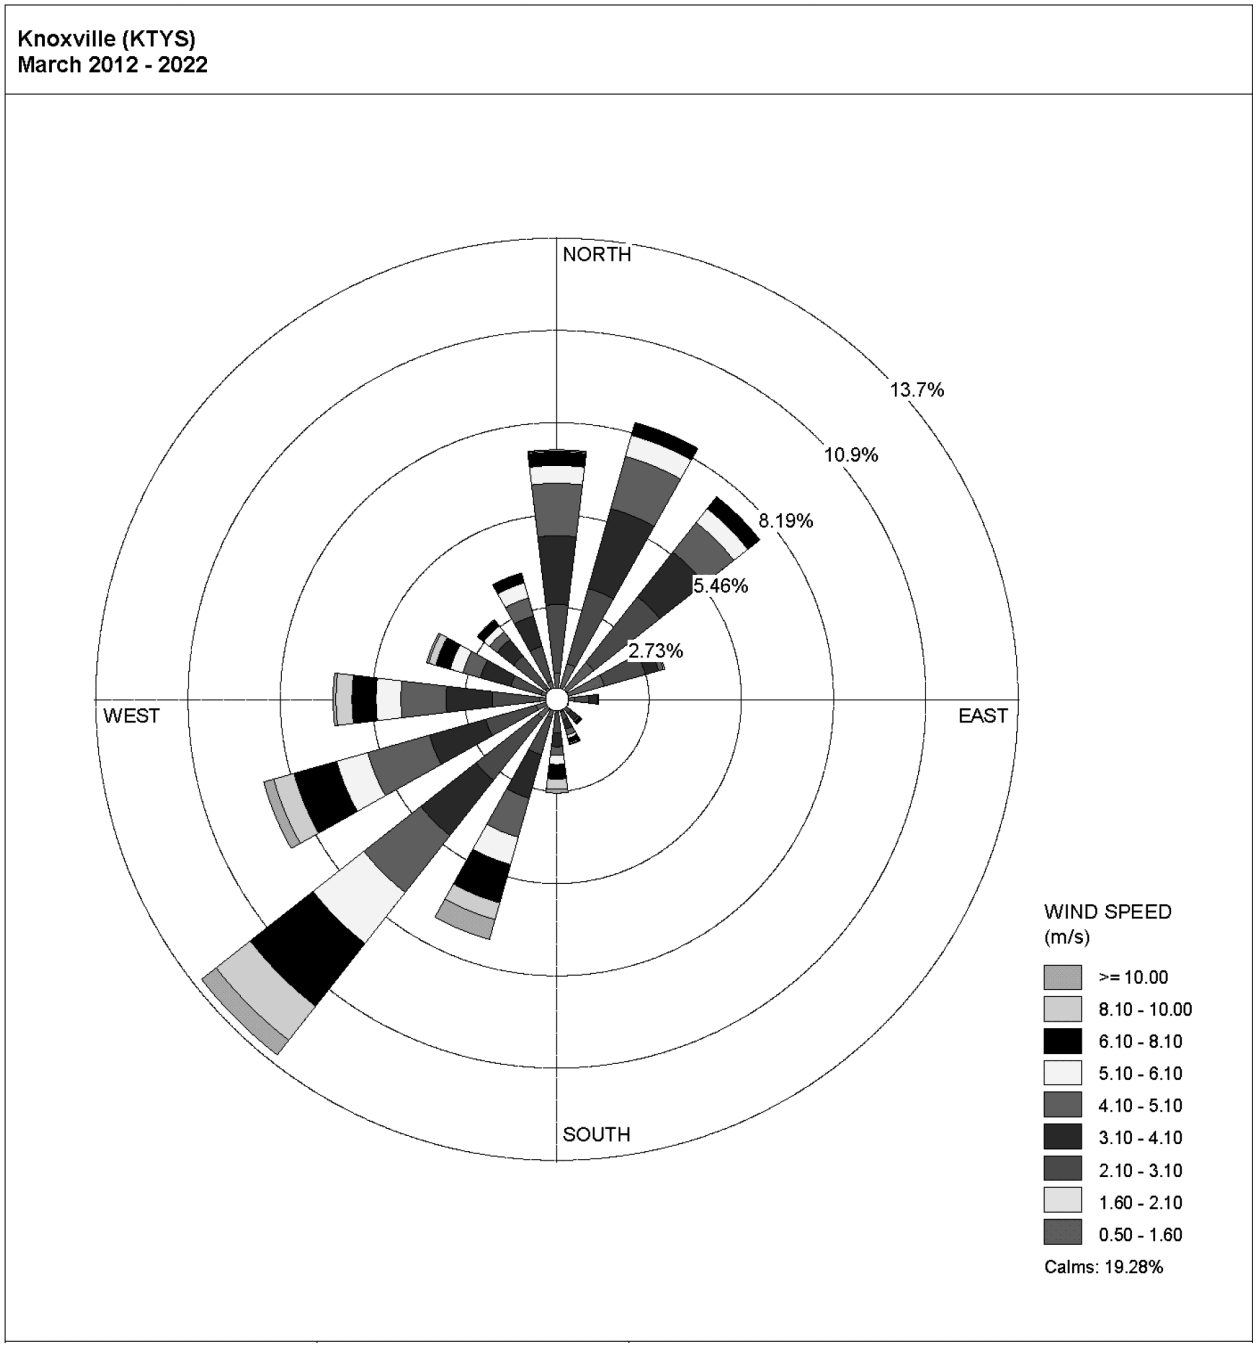

Figure 2.3.2-58R Wind Rose Knoxville 10 Years (2012–2022) March

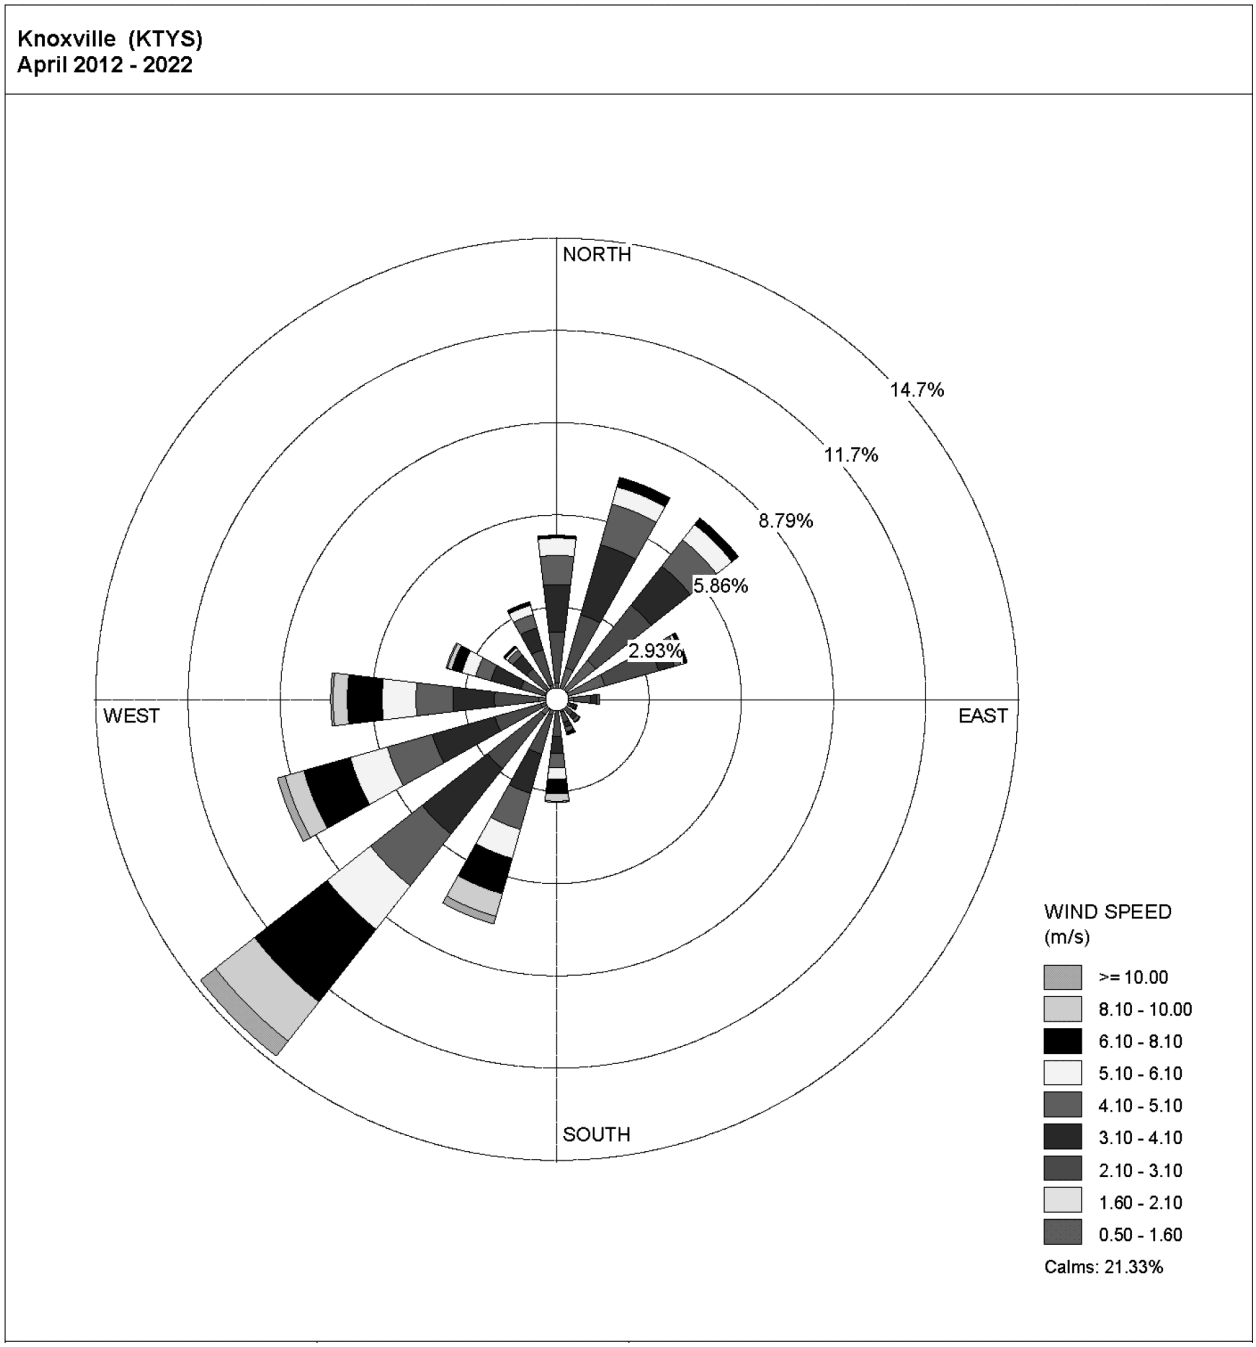

Figure 2.3.2-59R Wind Rose Knoxville 10 Years (2012–2022) April

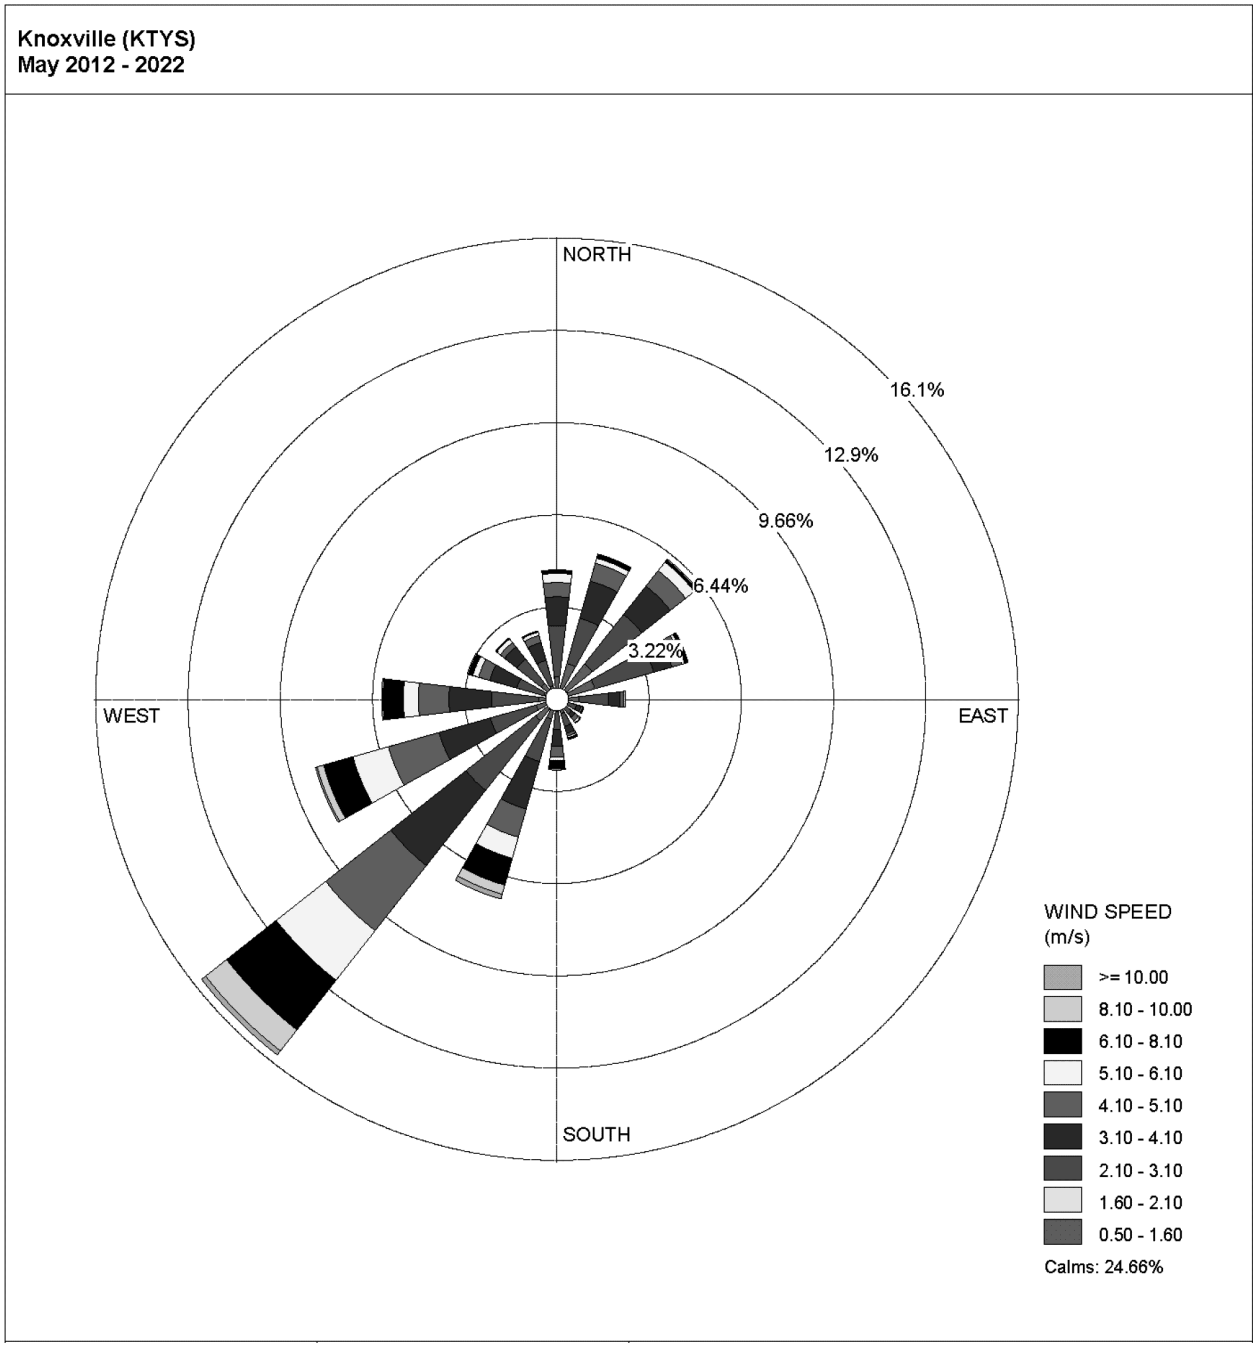

Figure 2.3.2-60R Wind Rose Knoxville 10 Years (2012–2022) May

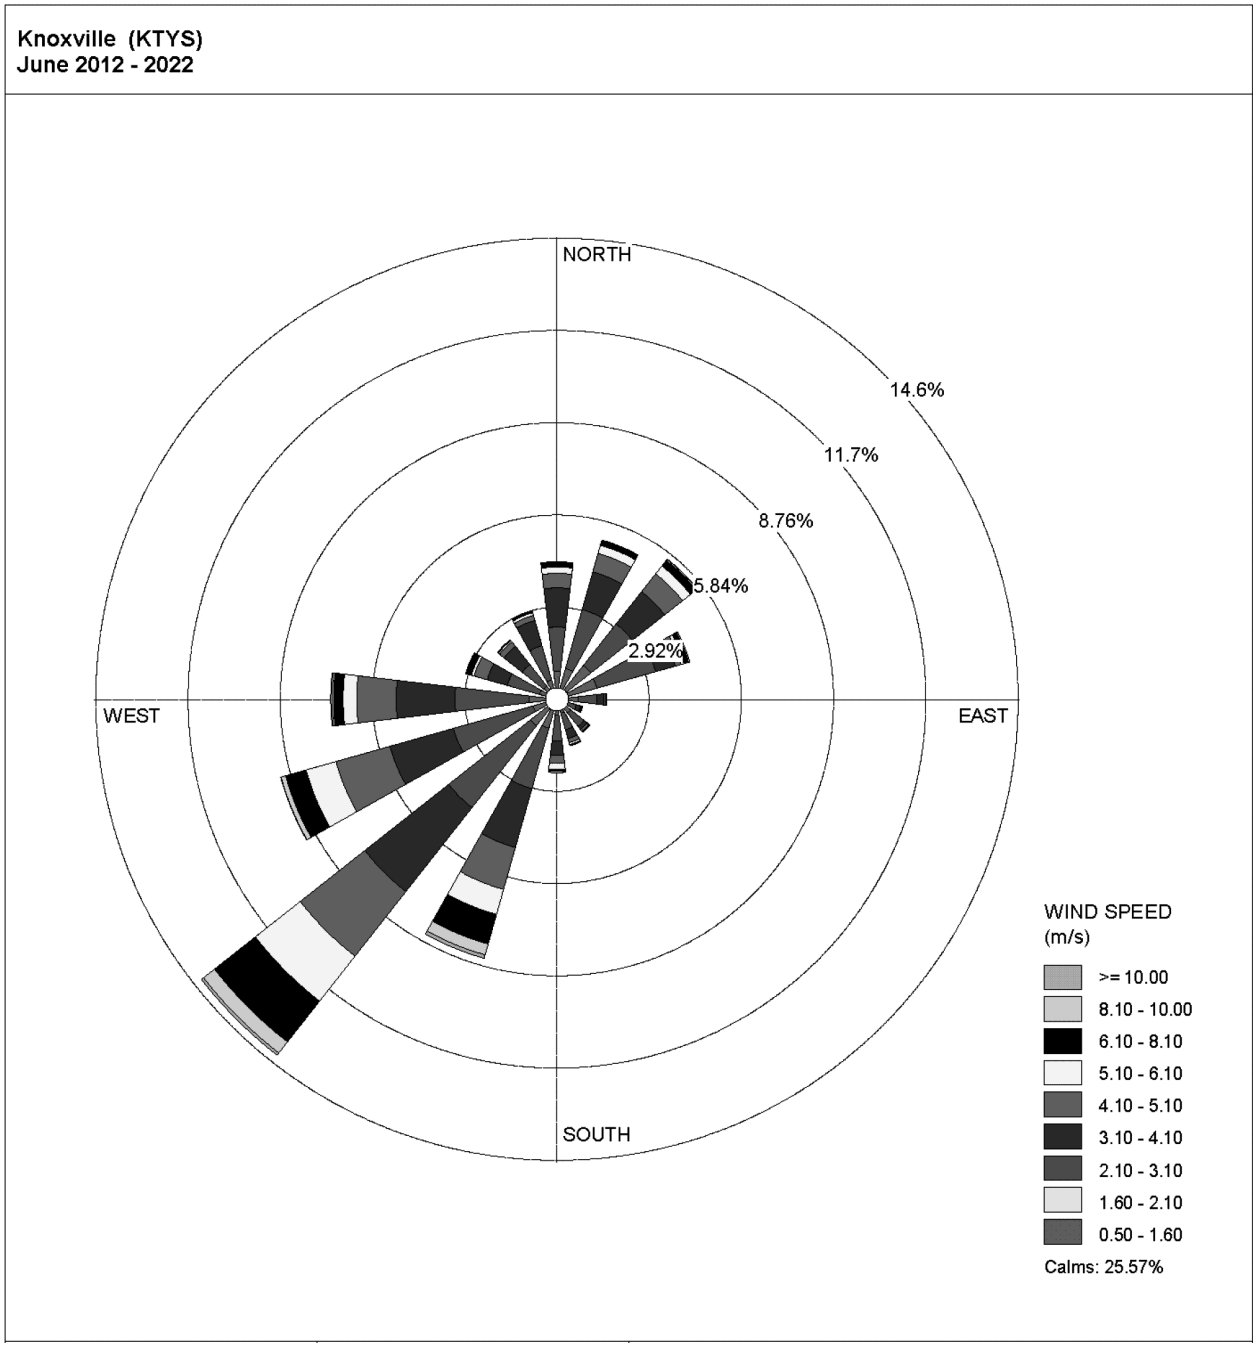

Figure 2.3.2-61R Wind Rose Knoxville 10 Years (2012–2022) June

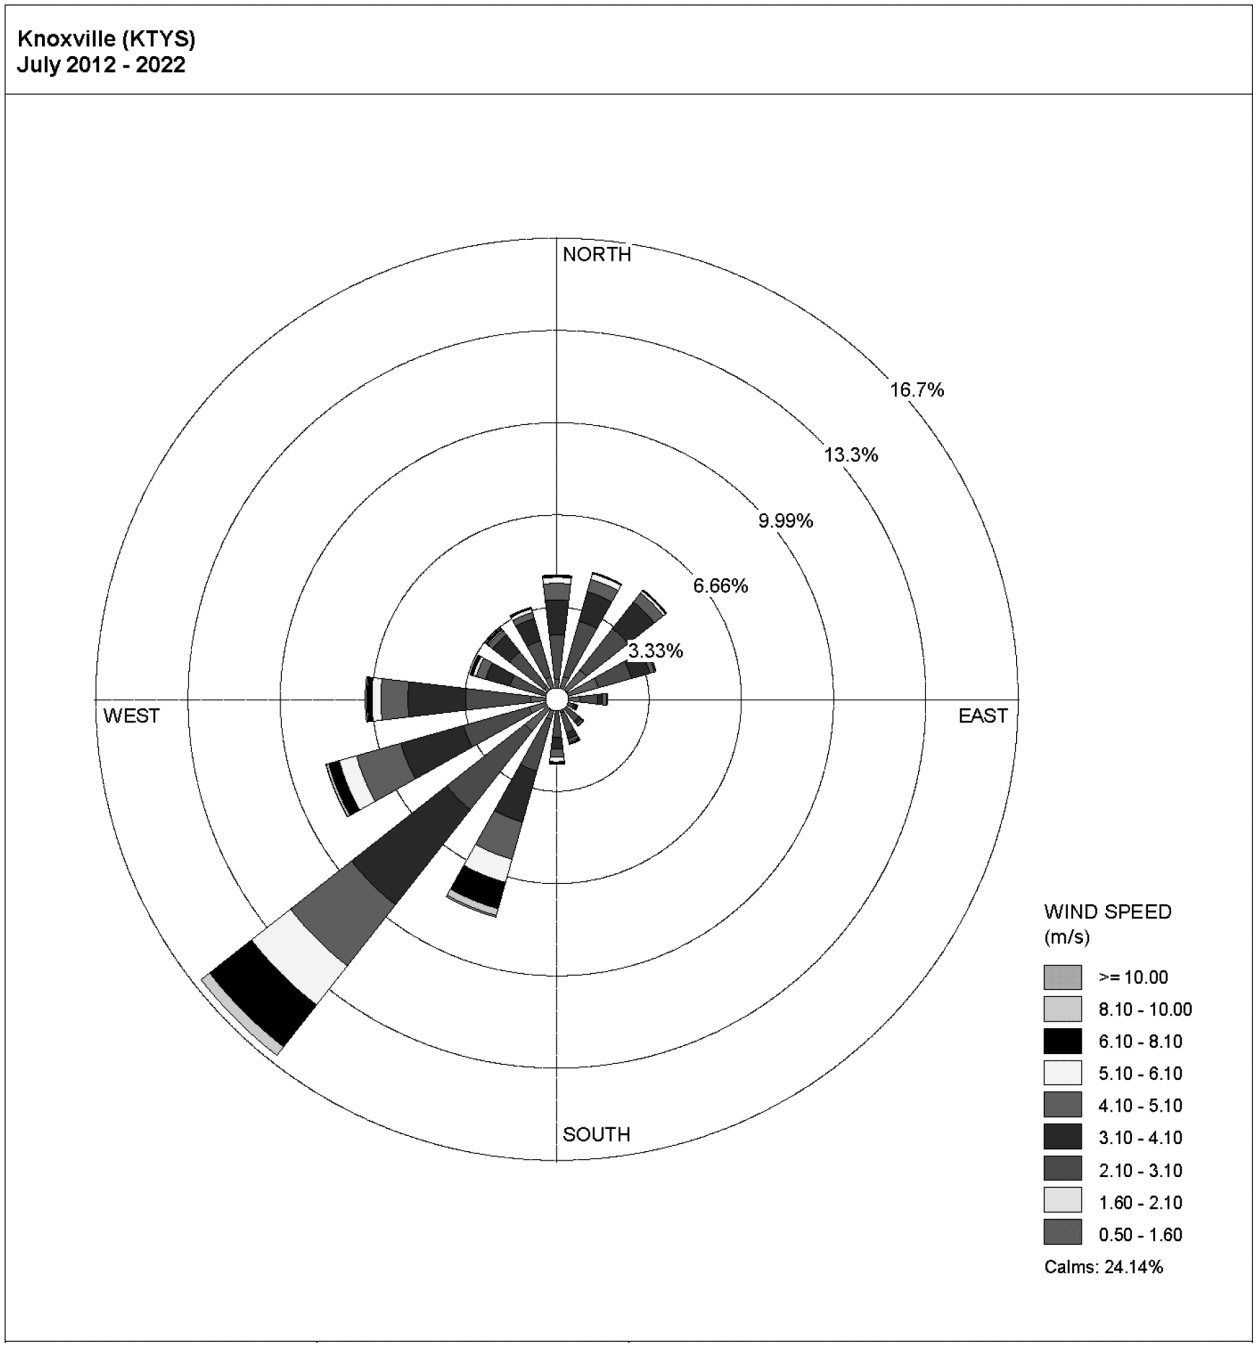

Figure 2.3.2-62R Wind Rose Knoxville 10 Years (2012–2022) July

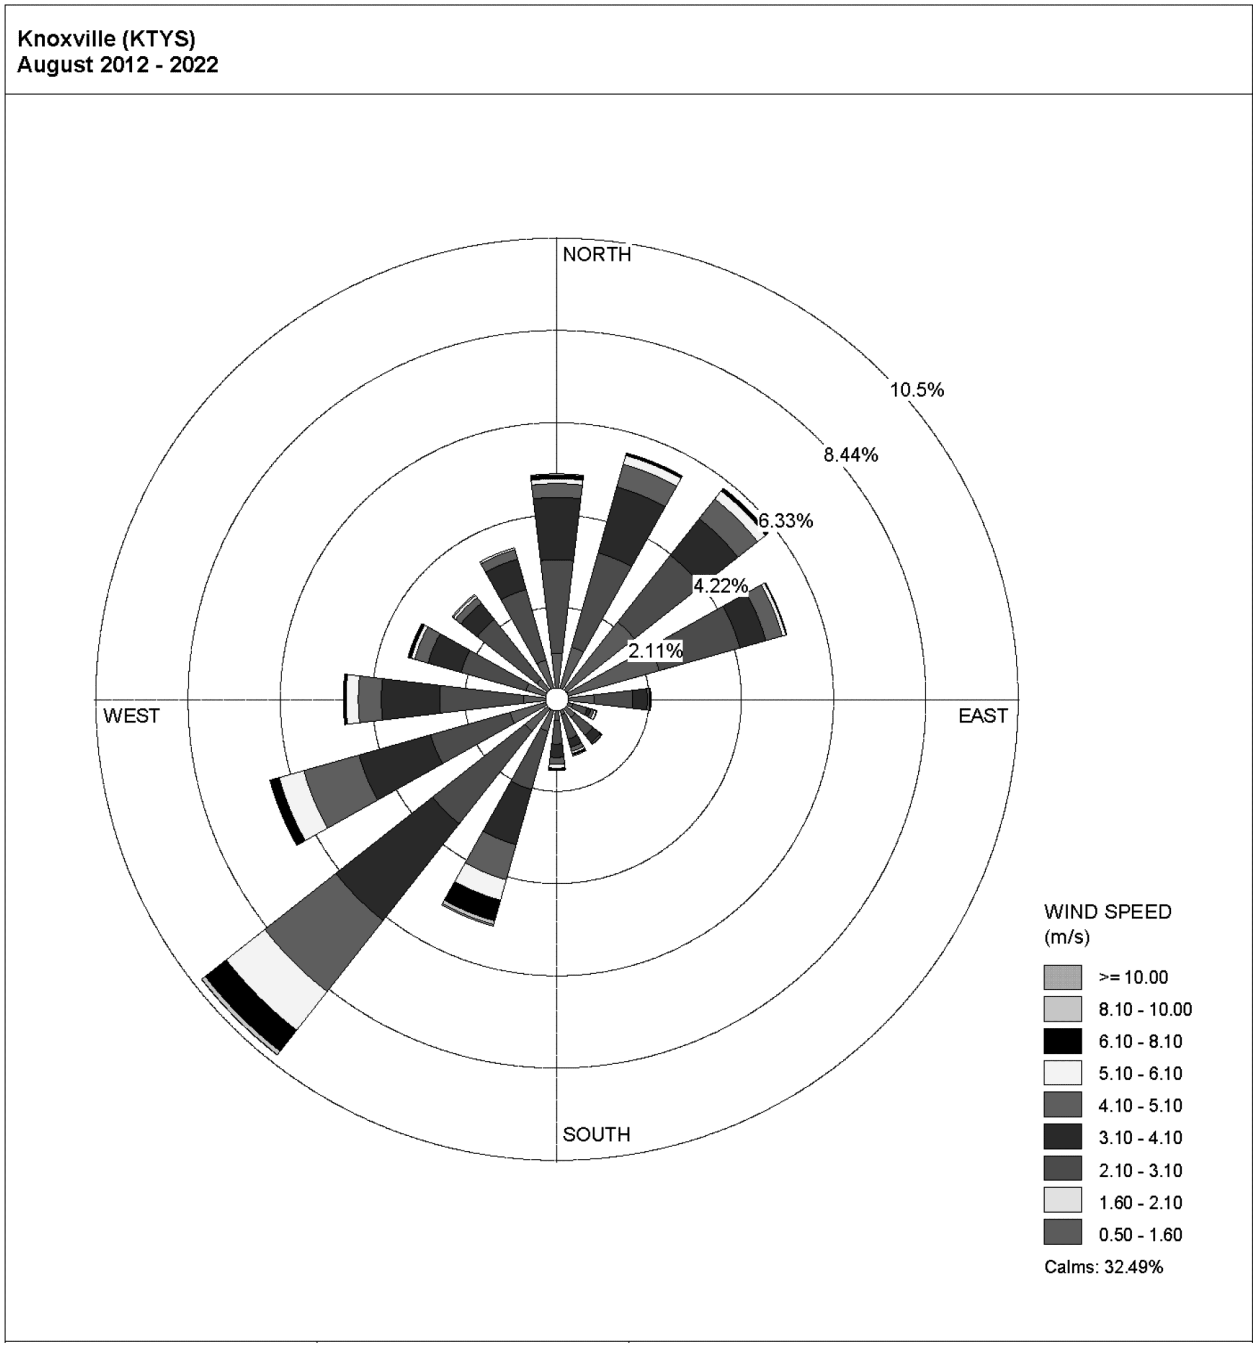

Figure 2.3.2-63R Wind Rose Knoxville 10 Years (2012–2022) August

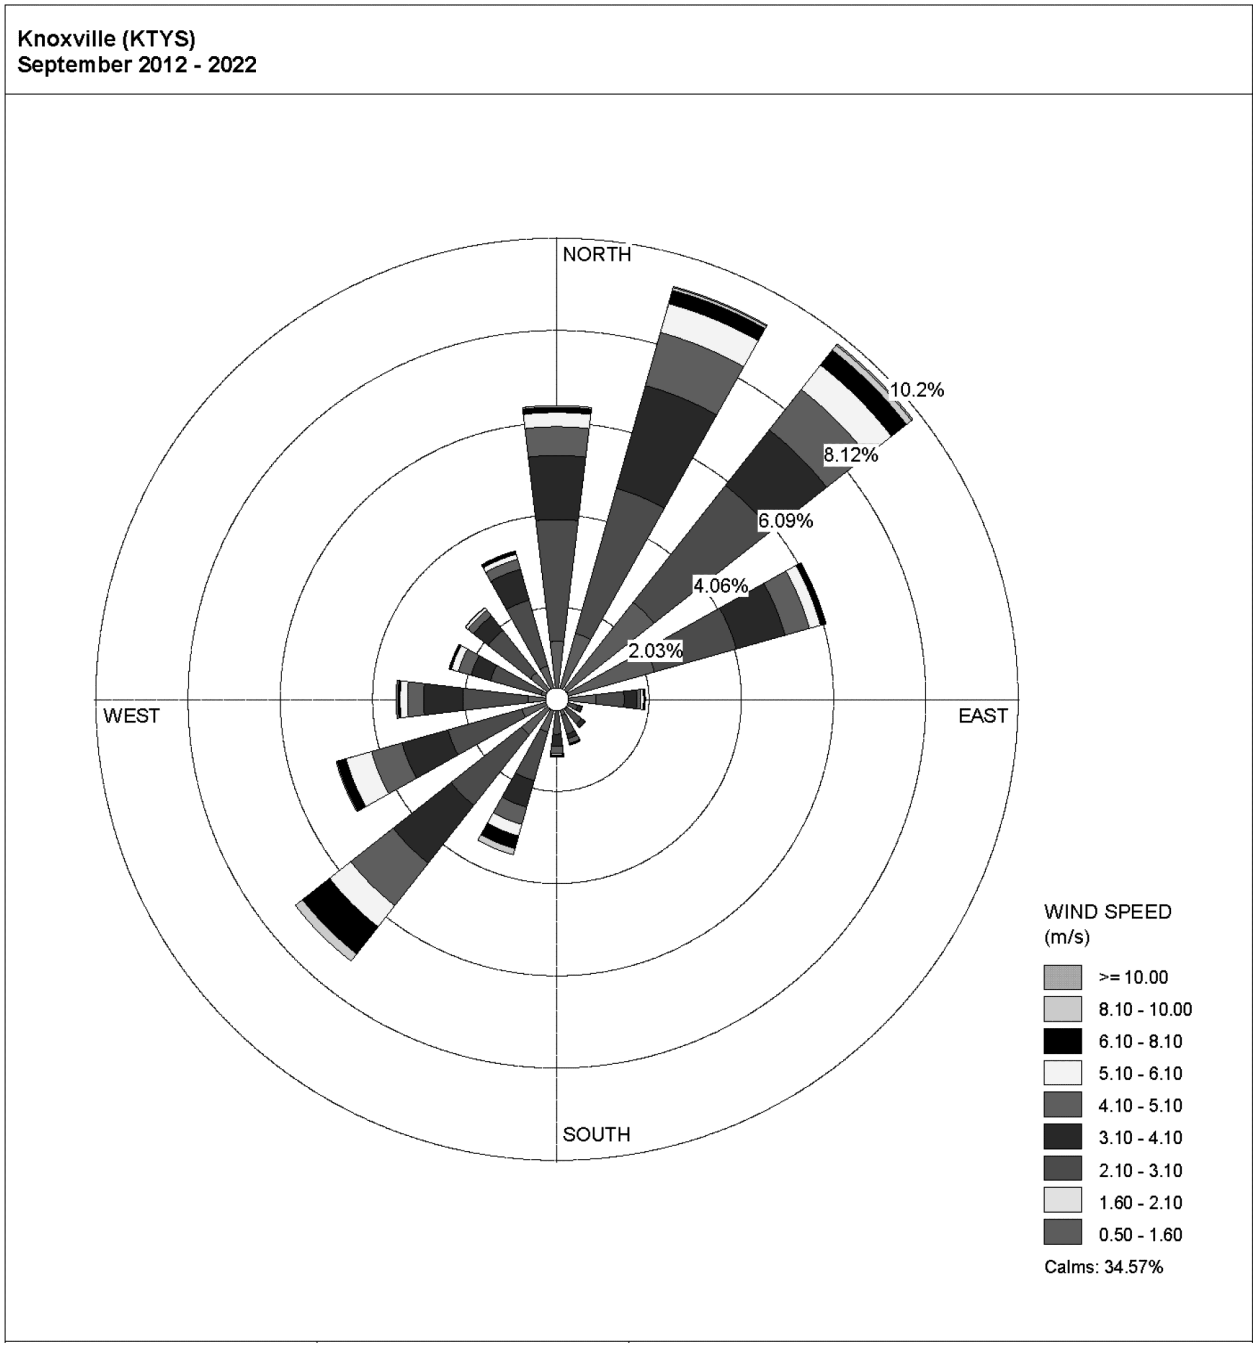

Figure 2.3.2-64R Wind Rose Knoxville 10 Years (2012–2022) September

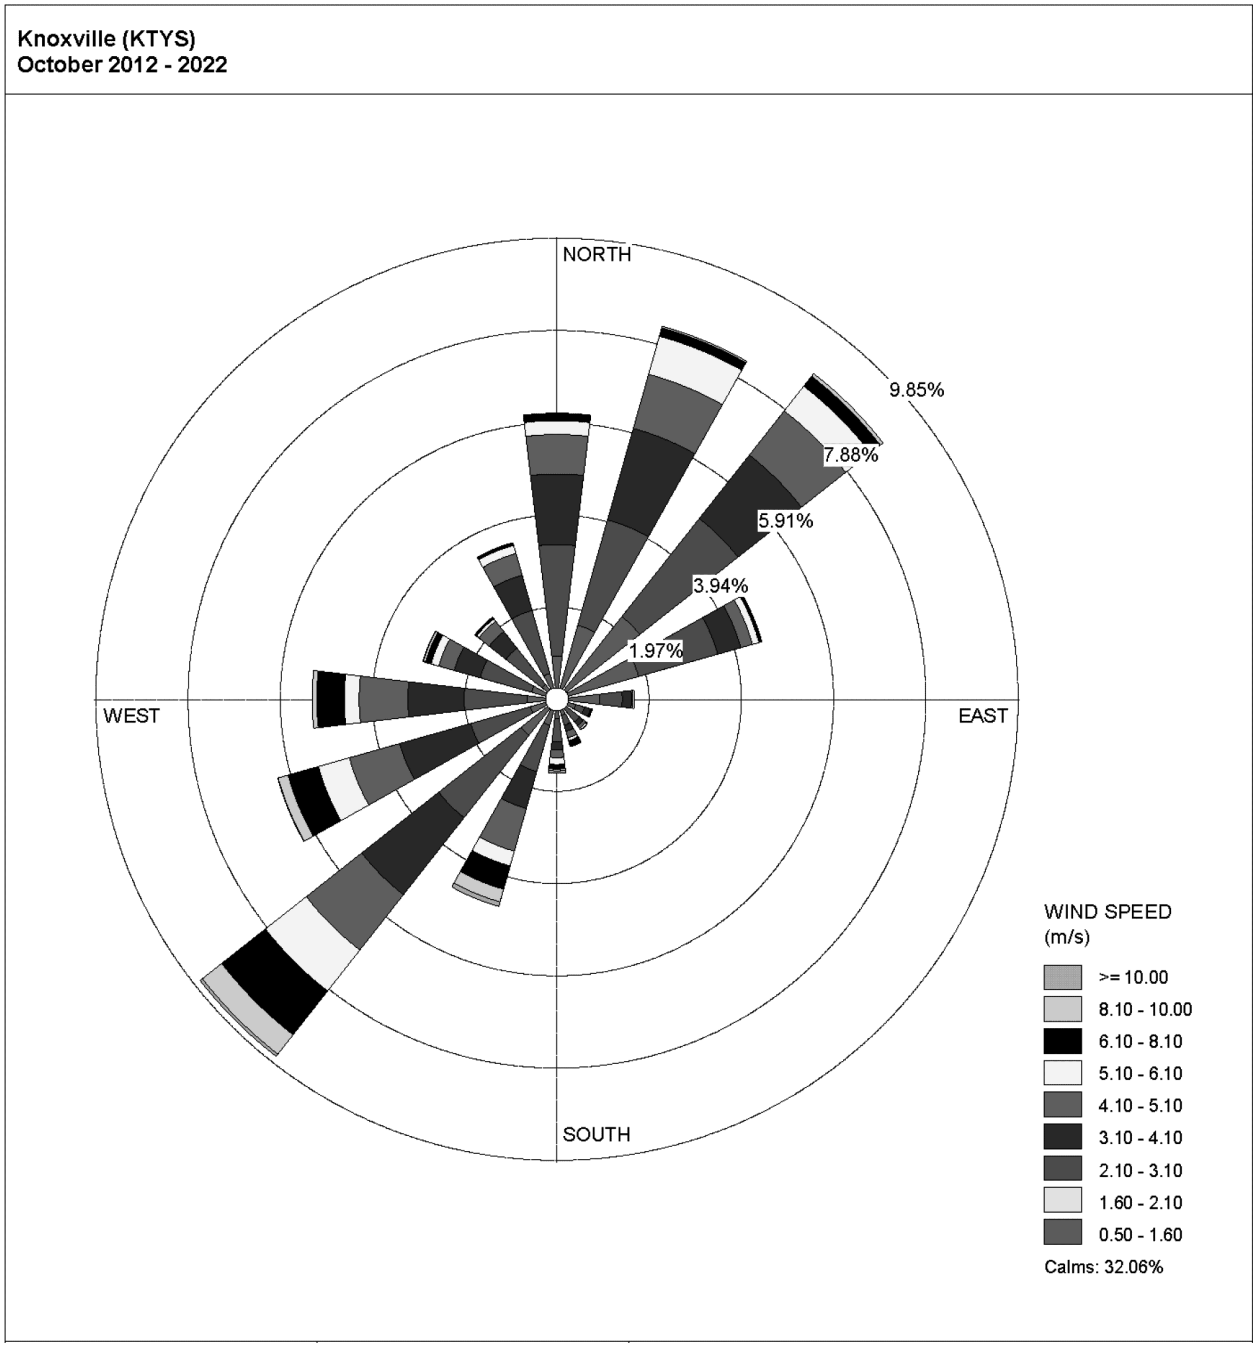

Figure 2.3.2-65R Wind Rose Knoxville 10 Years (2012–2022) October

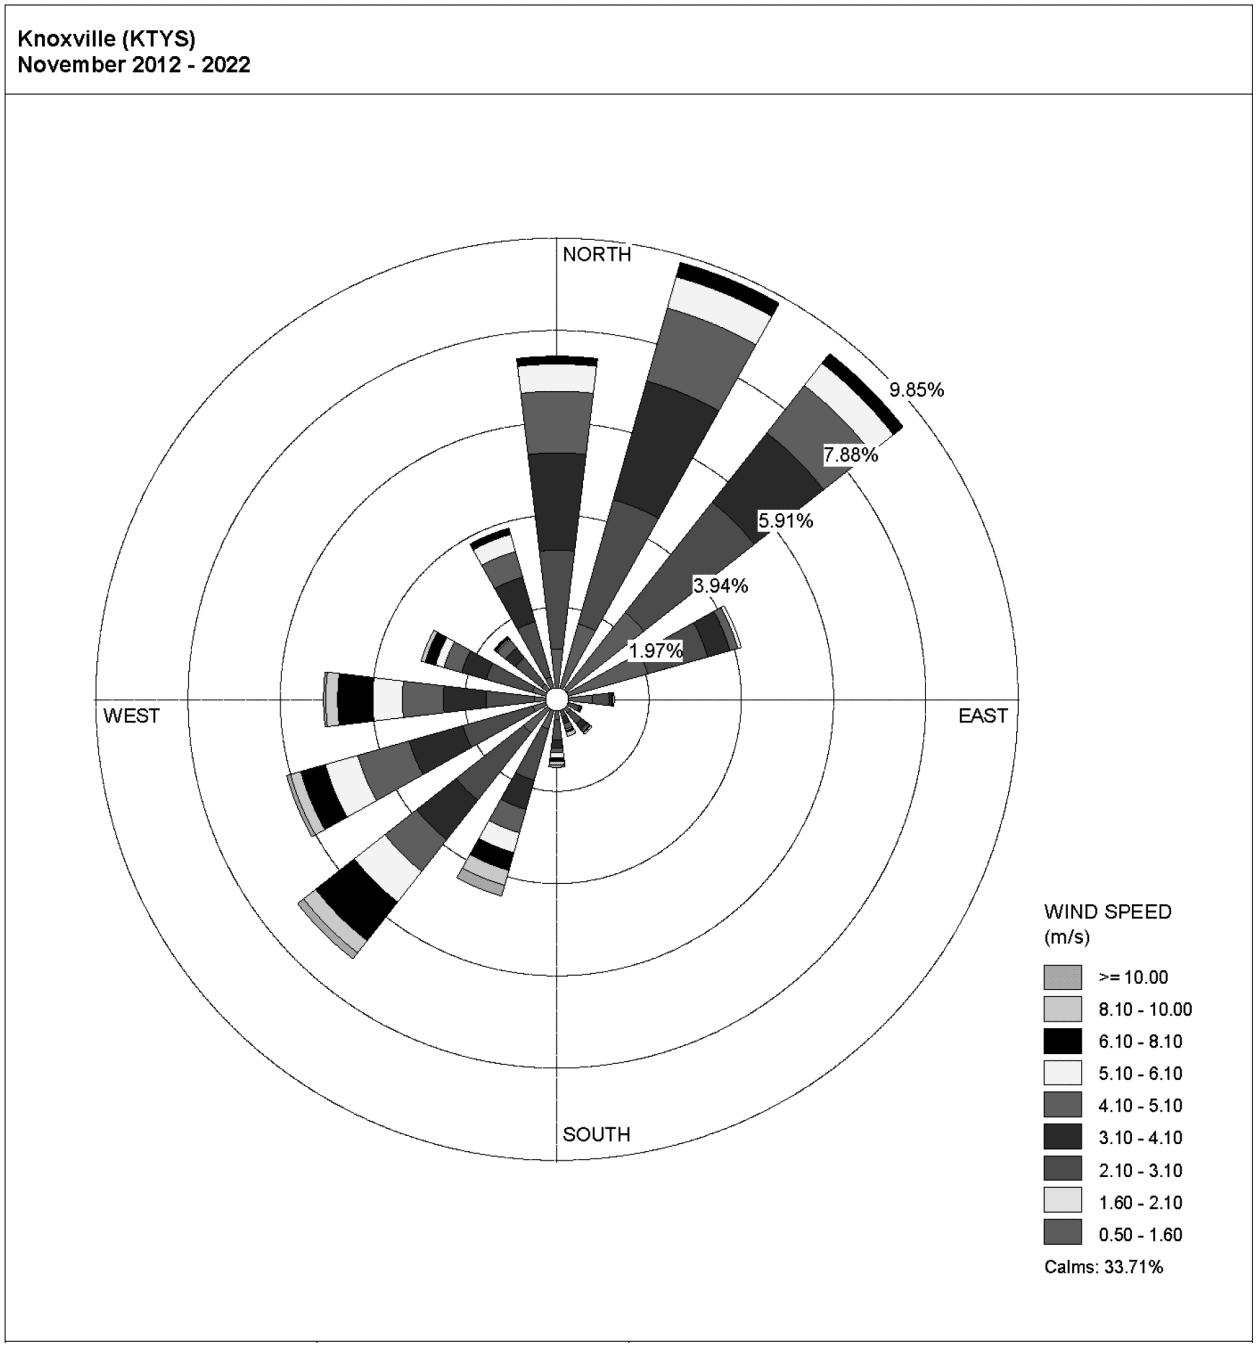

Figure 2.3.2-66R Wind Rose Knoxville 10 Years (2012–2022) November

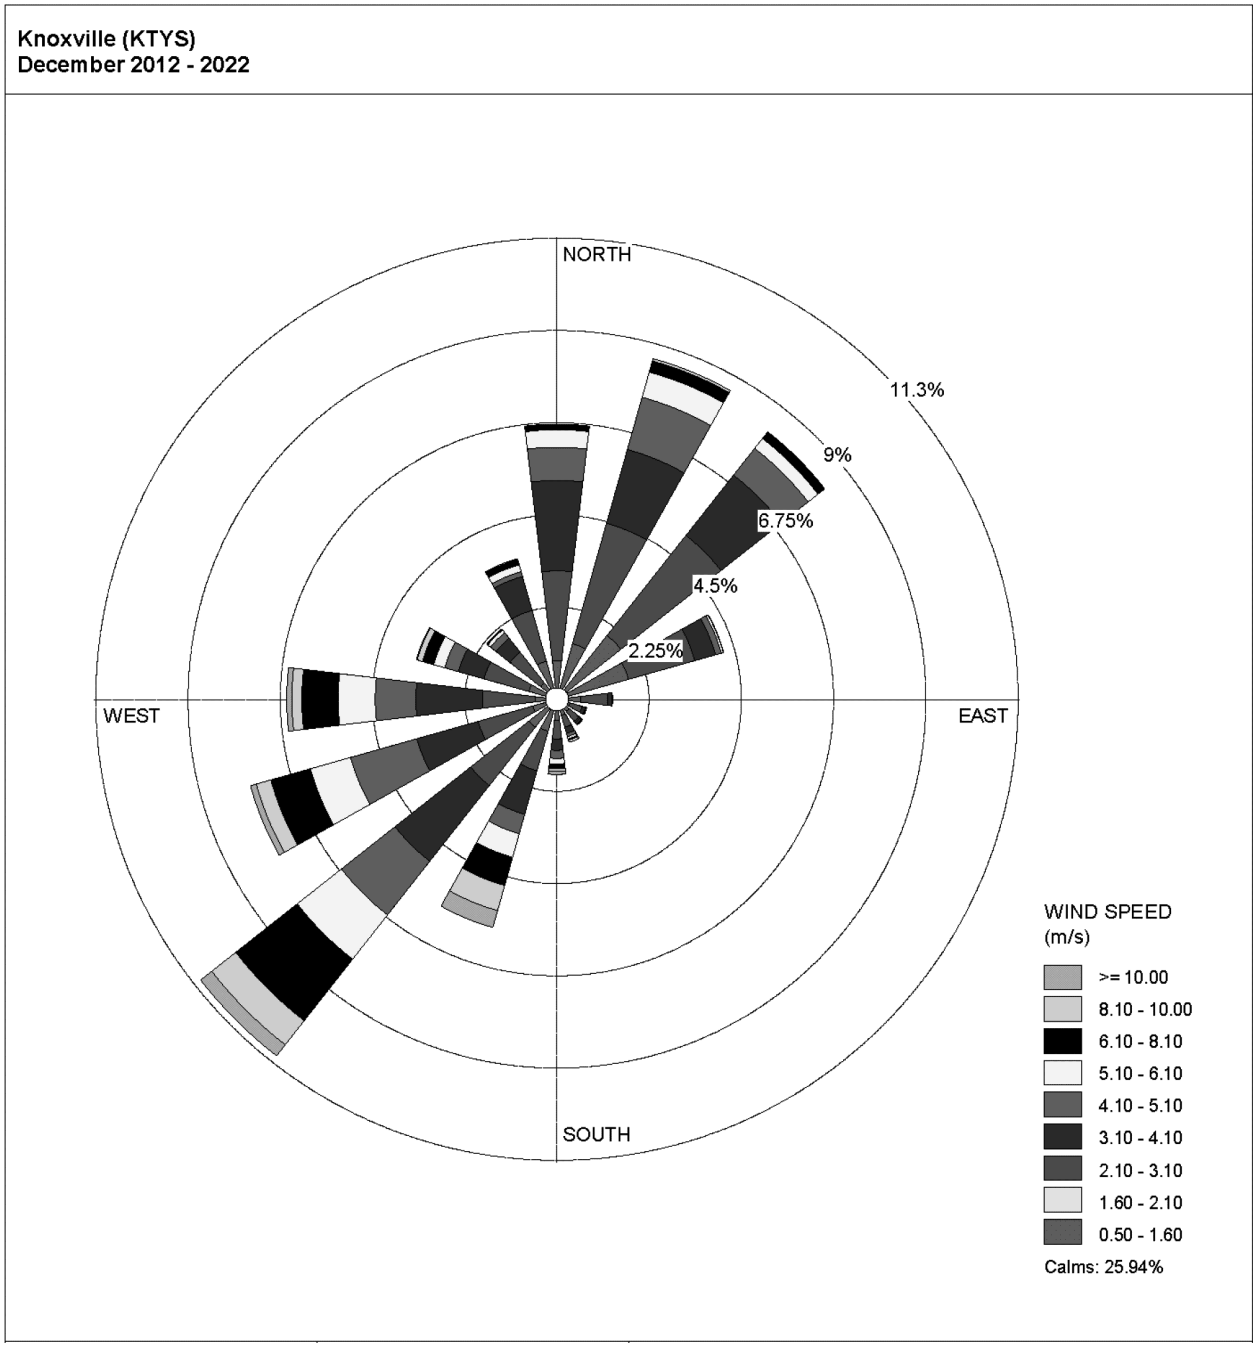

Figure 2.3.2-67R Wind Rose Knoxville 10 Years (2012–2022) December

Replace Figures 2.3.2-65 through 2.3.2-70 with Figure 2.3.2-78R through Figure 2.3.2-82R:

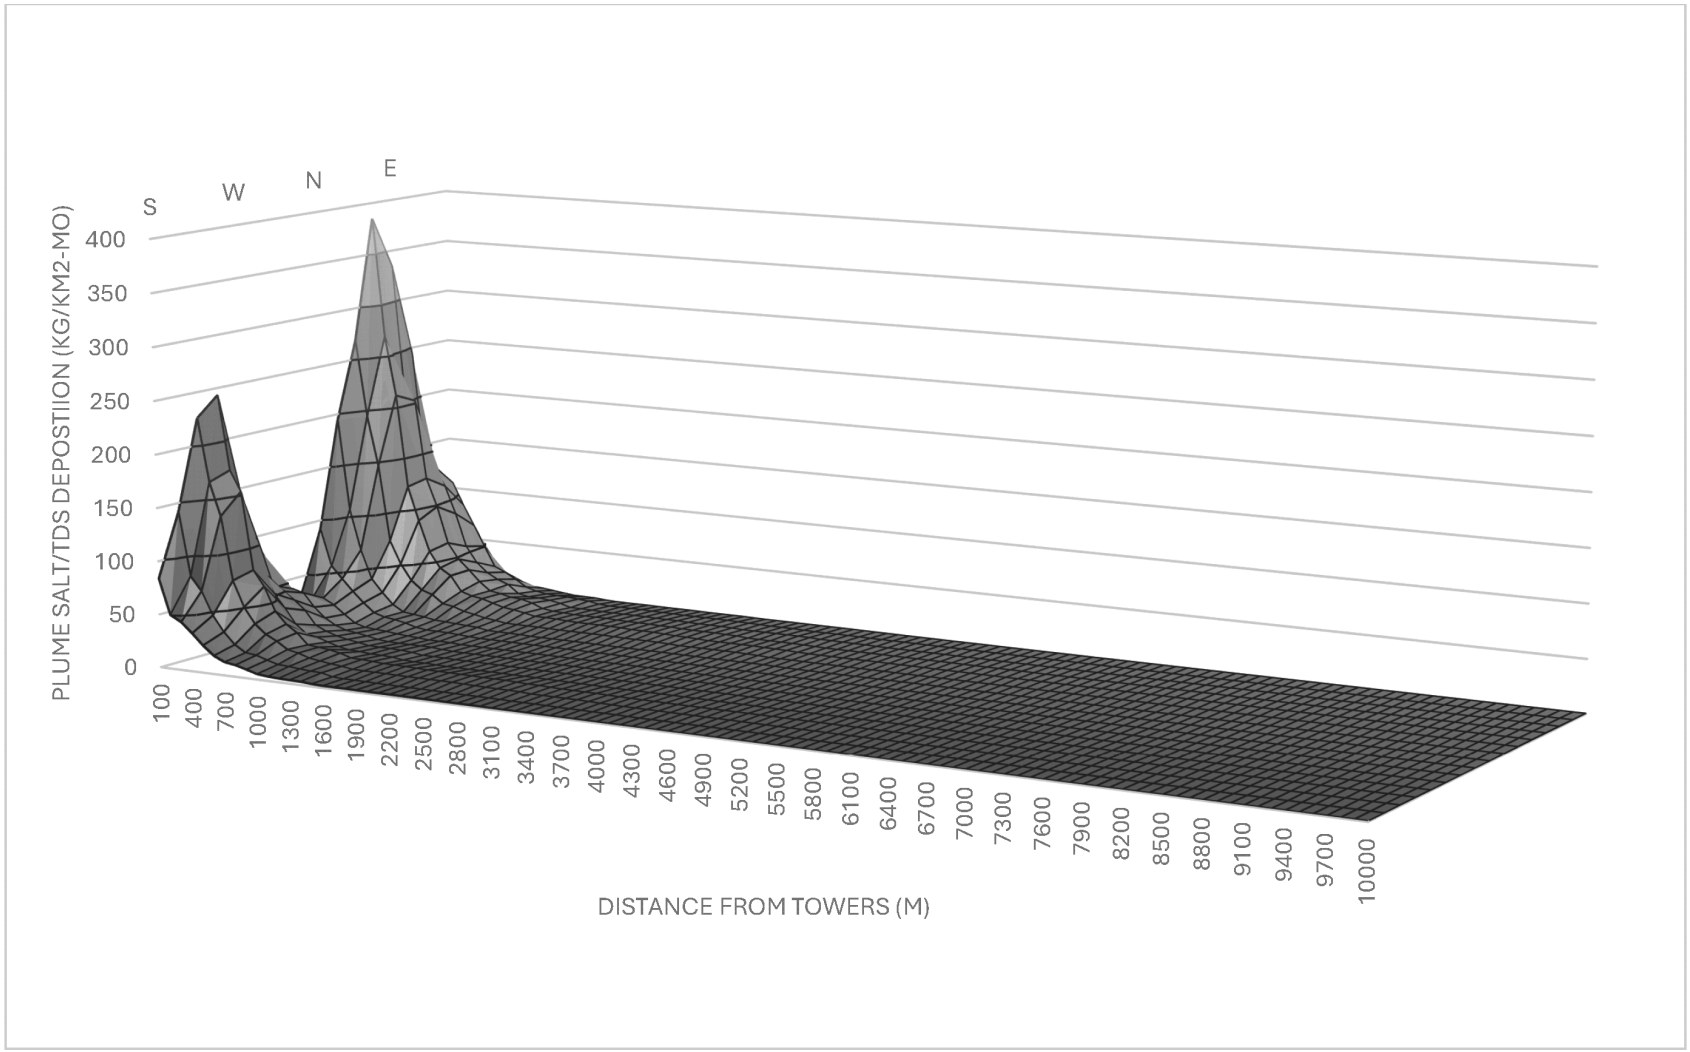

Figure 2.3.2-78R Annual Salt/TDS Deposition – Single Tower (CRN Tower) in kg/km^2/month

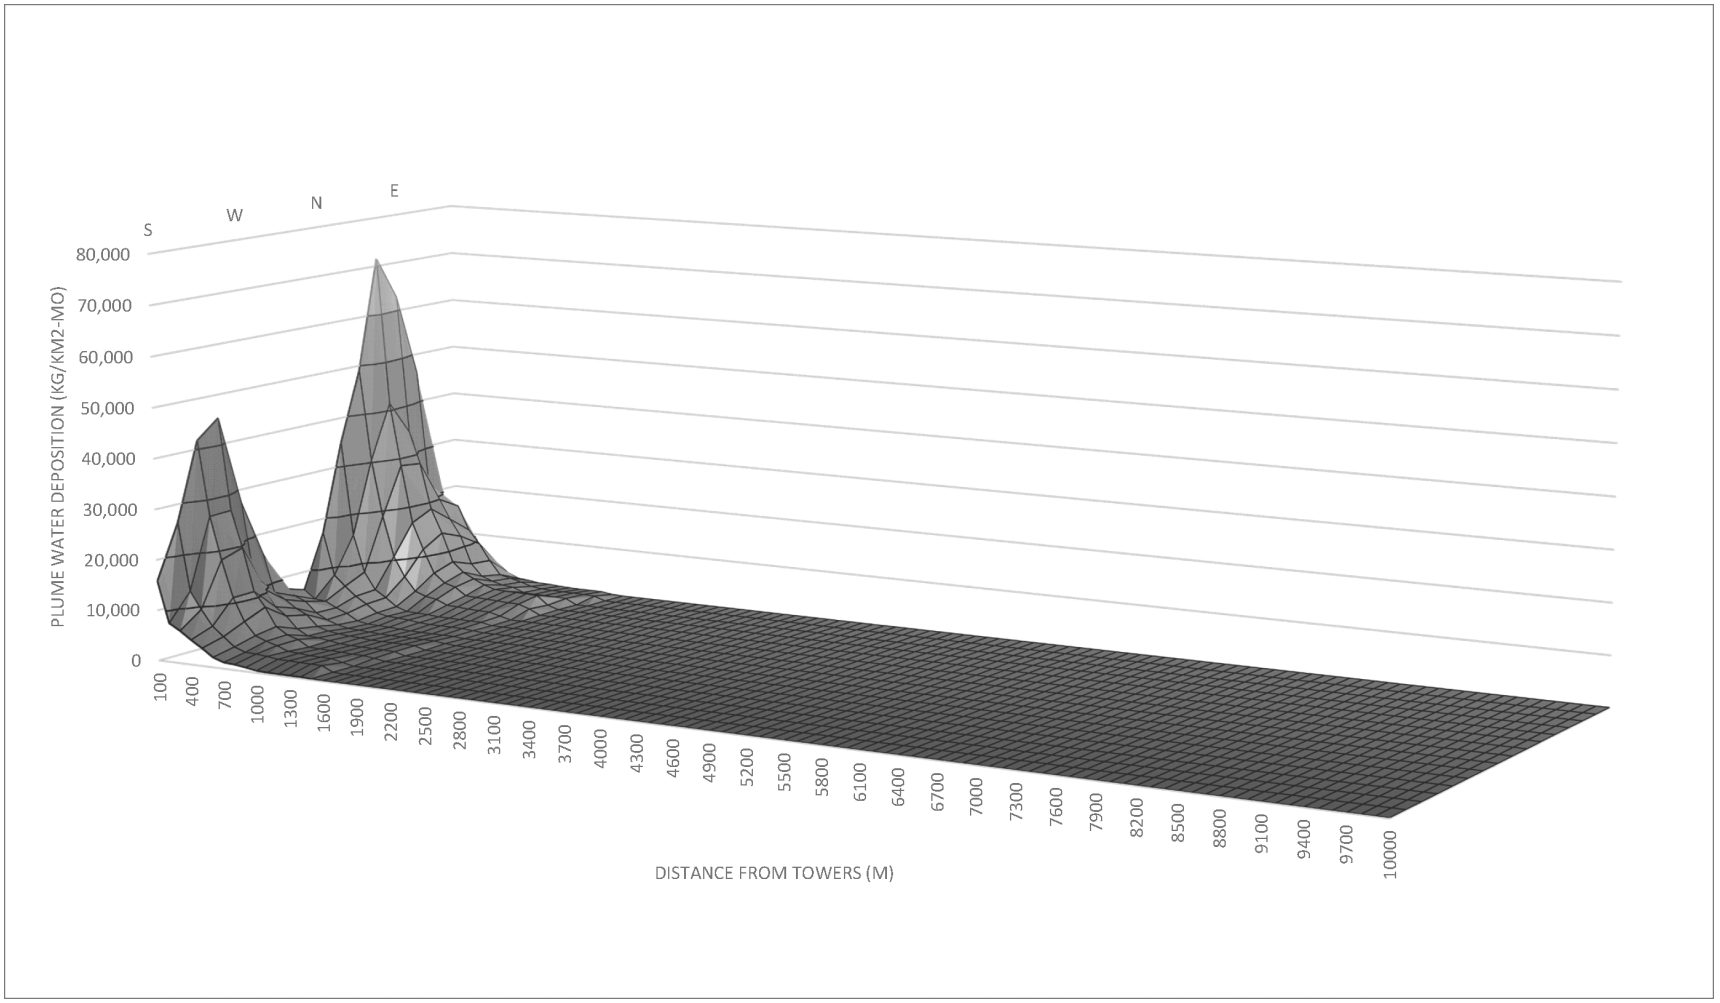

Figure 2.3.2-79R Annual Water Deposition – Single Tower (CRN Tower) in kg/km^2/month

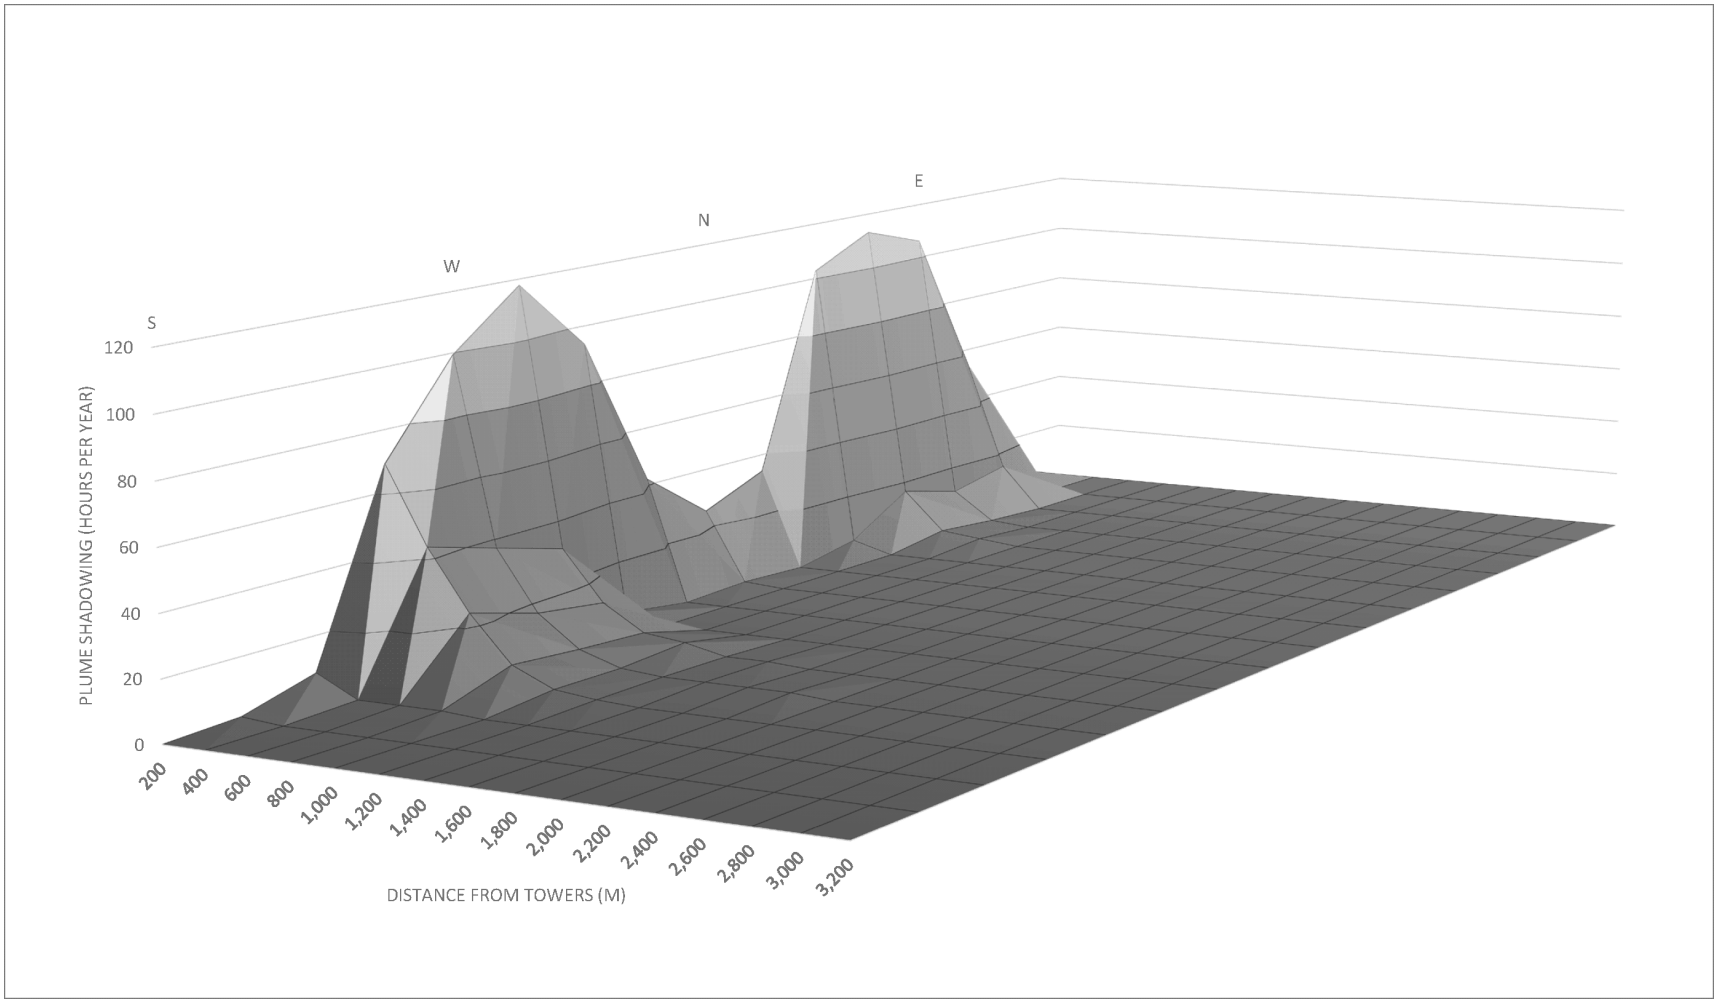

Figure 2.3.2-80R Annual Hours of Plume Shadowing – Single Tower (CRN Tower)

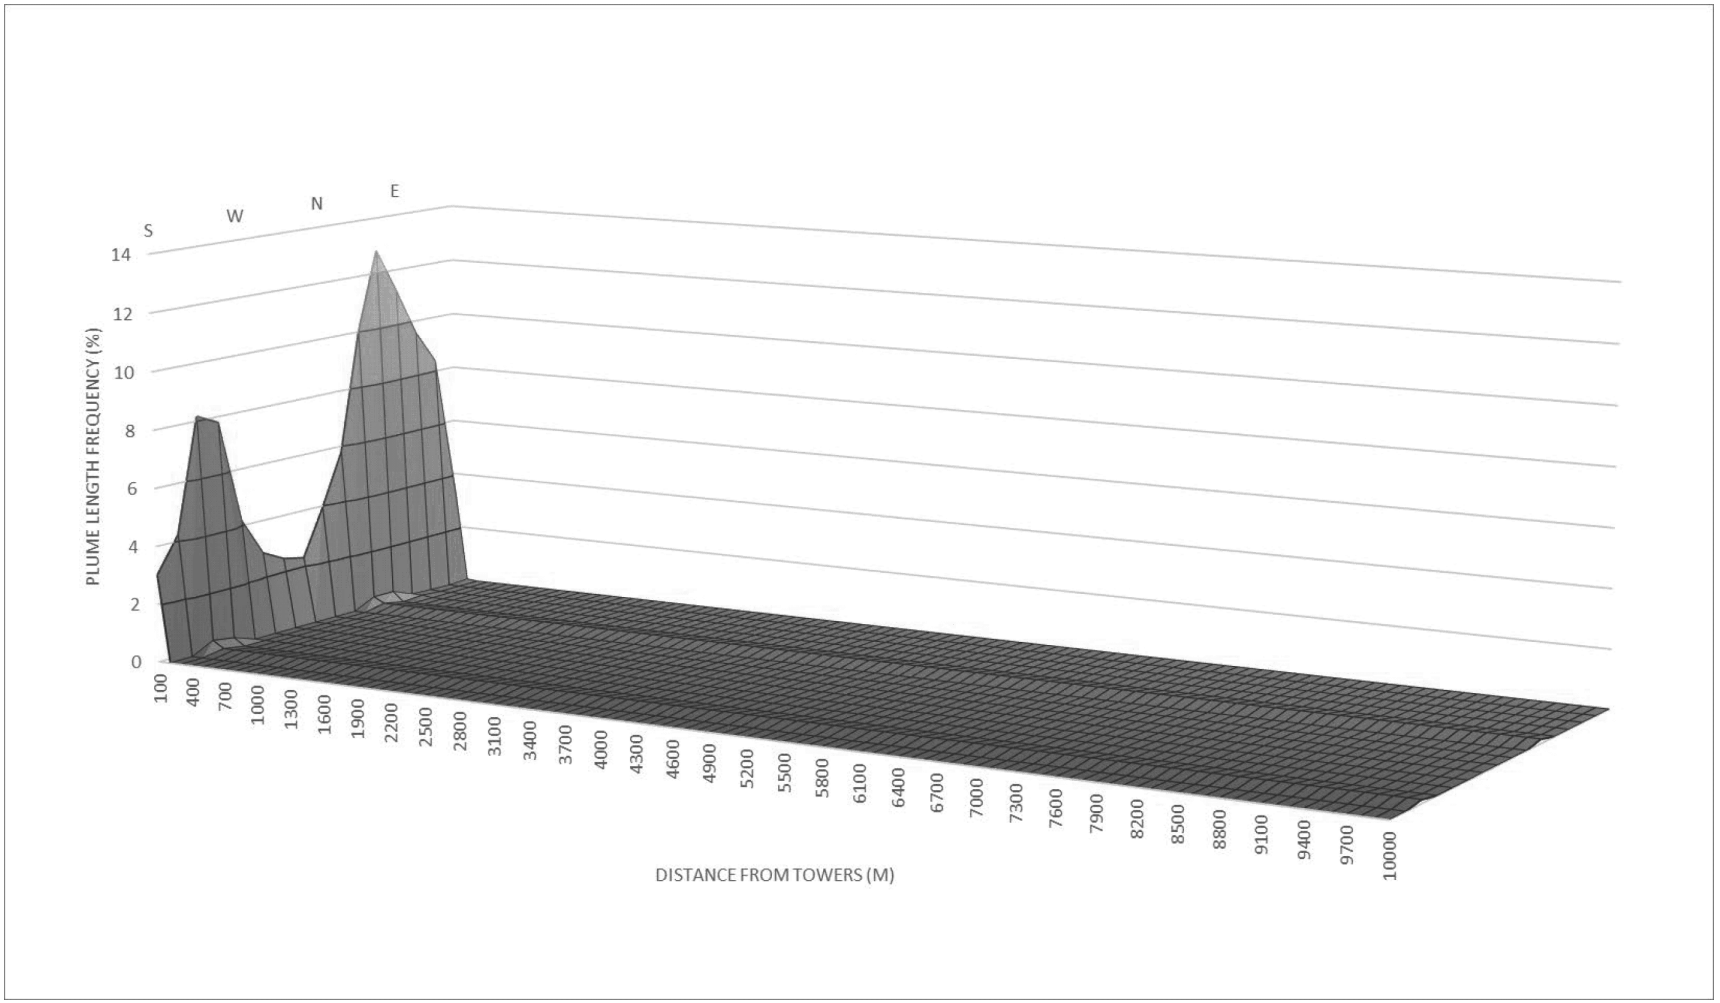

Figure 2.3.2-81R Annual Plume Length Frequency – Single Tower (CRN Tower)

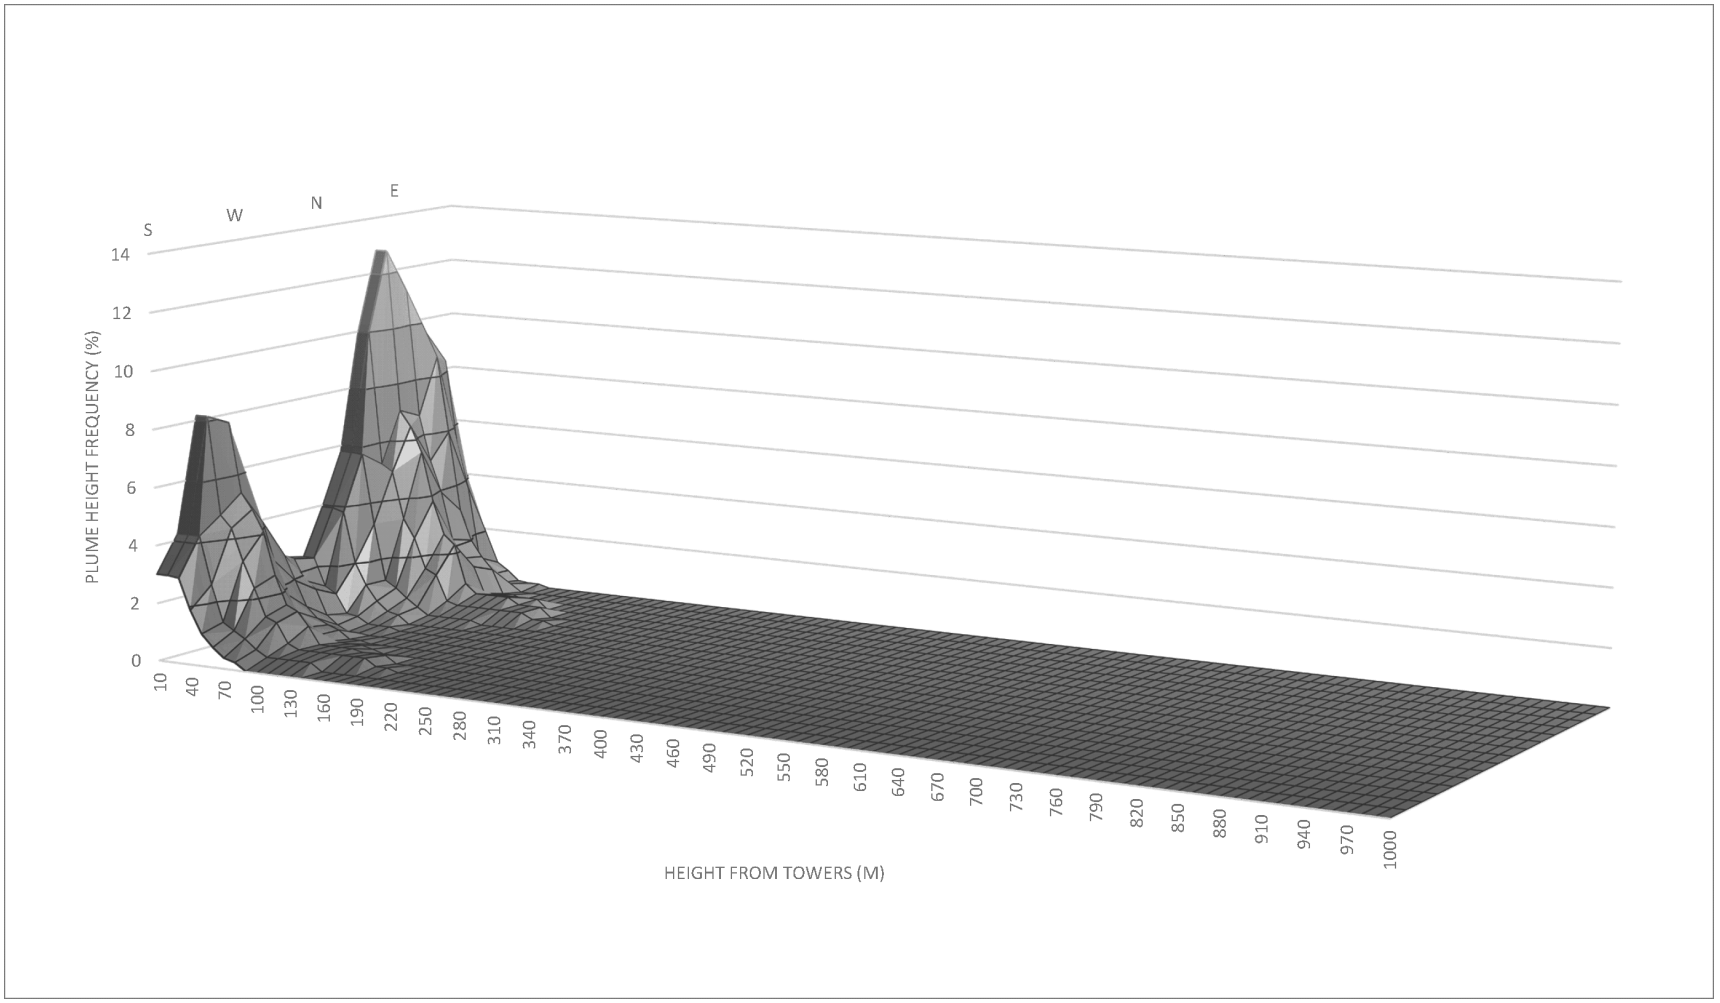

Figure 2.3.2-82R Annual Plume Height Frequency – Single Tower (CRN Tower)

2.3.3 Onsite Meteorological Measurements Program

Insert the following after the first paragraph in ESPA SSAR Section 2.3.3 (Addresses ESP COL Action Items 2.3-2, 2.3-3 and 2.3-4):

Subsequent to USNRC issuance of the early site permit for the CRN Site, TVA selected the GEH BWRX-300 reactor technology for evaluation at the CRN Site. The three years of existing onsite meteorological data for the CRN site used in the ESPA SSAR provide conservative and representative data for use in the construction permit. The existing onsite meteorological data as presented in ESPA SSAR Section 2.3.3 is used for subsequent evaluation of the BWRX-300 design in the construction permit application.

A new meteorological tower will be installed to collect data during the CRN Site operational phase. This tower, and the associated instrumentation, will be designed to meet the requirements of RG 1.23, Meteorological Monitoring Programs for Nuclear Power Plants. Meteorological data will be collected, consistent with the guidance of ANSI/ANS-3.11, Determining Meteorological Information at Nuclear Facilities, and retained for the life of the facility once a facility becomes operational at the CRN Site.

2.3.4 Short-Term (Accident) Diffusion Estimates

2.3.4.2 Calculation Methodology and Assumptions

Replace 1st sentence of the 2nd paragraph with the following:

SRP 2.3.3 recommends that the Applicant should provide meteorological data from at least two consecutive annual cycles, including the most recent one-year period for calculating the short-term and long-term atmospheric dispersion estimates.

2.3.5 Long-Term (Routine) Diffusion Estimates

2.3.5.2 Calculation Methodology and Assumptions

Replace 1st sentence of the 1st paragraph with the following:

SRP 2.3.3 recommends that the Applicant should provide meteorological data from at least two consecutive annual cycles, including the most recent one-year period for calculating the short-term and long-term atmospheric dispersion estimates.

2.4 Hydrologic Engineering

Section 2.4 of the referenced ESPA SSAR is incorporated by reference with the following supplements.

2.4.0 Hydrology Review

Replace the first and second sentences of the second paragraph of ESPA SSAR Section 2.4.0 with the following:

The CRN Site is located on the north bank of the Clinch River arm of Watts Bar Reservoir between Clinch River Mile (CRM) 19 to CRM 14.5 (Reference 2.4.1-1) with preliminary plant grade at elevation 814.5 feet (ft), referenced to the North American Vertical Datum of 1988 (NAVD88). A single BWRX-300 small modular reactor (SMR) developed by General Electric (GE) Hitachi (GEH) is planned for the CRN Site and included as Unit 1 in the Construction Permit Application. Final grade elevation will be established in consideration of requirements to provide flood protection for SC1 systems, structures and components (SSCs) in accordance with RG 1.59, Position 1.

2.4.1 Hydrologic Description

2.4.1.1 Site and Facilities

Replace the third sentence of the first paragraph of ESPA SSAR Section 2.4.1.1 with the following:

[

]

Replace the fifth sentence of the third paragraph of ESPA SSAR Section 2.4.1.1 with the following:

The river would not supply any SC1 systems.

2.4.1.2.2 Groundwater

Replace the first sentence of the first paragraph of ESPA SSAR Section 2.4.1.2.2 with the following:

Subsection 2.4.12 contains a detailed description of the hydrogeologic conditions at and in the vicinity of the CRN Site and includes the regional and local groundwater resources that could be affected by the construction and operation of BWRX-300 SMR at the CRN Site.

2.4.2 Floods

2.4.2.2 Flood Design Considerations

Replace the last sentence of the Flooding from Landslides section of ESPA SSAR Section 2.4.2.2 with the following (Addresses COL Action Item 2.4-2):

[

]

2.4.2.3 Effects of Local Intense Precipitation

Replace ESPA SSAR Section 2.4.2.3 with the following (Addresses COL Action Item 2.4-1):

[

]

[

]

2.4.2.3.1 Precipitation Distribution

Replace ESPA SSAR Section 2.4.2.3.1 with the following:

The LIP depths for the plant were determined from guidance presented in Hydro-Meteorological Report No. 56 and No. 52 (HMR-56 and HMR-52) (References 2.4.2-2 and 2.4.2-1, respectively). The guidelines set forth in HMR-56 and HMR-52 were followed to form the rainfall hyetograph of the 1-hour (hr), 1-sq mi PMP for CRN. PMP rainfall values in HMR-56 were chosen based on the terrain distribution roughness of the site, as shown in Figure 68 of Reference 2.4.2-2. The CRN Site falls in the rough zones in Figure 68.

The base LIP hyetograph for the CRN Site is determined by adjusting the “rough terrain” precipitation depths in Table 6 of HMR-56. The moisture reduction index factor of 95.6 percent from HMR-56, Figure 20, representative of the CRN Site location was omitted, and rainfall is therefore conservative.

A rainfall depth-duration curve was created using depths from HMR-56 for 5-minute increments up to 1-hour duration. Times of concentration were determined for the respective site sub-watersheds and corresponding rainfall depths from the depth-duration curve were applied as steady state. The cumulative rainfall values are summarized in Table 2.4.2-2R. Additional analysis will be performed at OLA.

2.4.2.3.2 Runoff Model

Replace ESPA SSAR Section 2.4.2.3.2 with the following:

Runoff was assumed at 100% of rainfall with constant peak flow using a Rational Method approach. The site layout and facilities at the CRN Site have not been finalized. Thus, the final runoff model has not been developed. This task would be performed as part of detailed engineering included with the OLA.

2.4.2.4 Site Drainage System

Replace ESPA SSAR Section 2.4.2.4 with the following:

The location and design of stormwater conveyance facilities have not been determined. These tasks would be performed as part of detailed engineering at OLA. Stormwater would be carried away from the plant area by a stormwater collection system comprising appropriate combinations of swales, open channels, or a subsurface system of catch basins, pipes and culverts. Runoff would be routed to the Watts Bar Reservoir. However, the finished grade for the site would slope away from buildings and be designed such that the peak discharges from the LIP would not flood SC1 facilities if the subsurface drainage system were plugged.

Replace Table 2.4.2-2 with the following:

Table 2.4.2-2R Clinch River Nuclear Site Local Intense Precipitation Values—1-hr, 1-sq mi Probable Maximum Precipitation

Sub-Watershed	Time of Concentration (minutes)	Model Rainfall Depth (inches)	Rainfall Intensity (inches/hour)
A	14.48	7.92	32.79
B	17.04	8.83	31.10
C	16.38	8.60	31.51
D	8.20	5.19	37.97
E	13.79	7.65	33.29
F	14.48	7.91	32.79
G	11.33	6.65	35.22
H	15.34	8.23	32.19

2.4.3 Probable Maximum Flood (PMF) on Streams and Rivers

2.4.3.7 Coincident Wind Wave Activity

Replace the fifth sentence of the second paragraph of ESPA SSAR Section 2.4.3.7 with the following:

The effective fetch found for the CRN Site from available GIS terrain data was 4.25 mi, based on the site grade elevation of 814.5 ft, and results in the critical site fetch length (Figure 2.4.3-16).

Replace the seventh sentence of the second paragraph of ESPA SSAR Section 2.4.3.7 with the following:

CRN Site grade is 814.5 ft NAVD88 (814.9 ft NGVD29), 8.9 ft higher than the maximum calculated water surface elevation with wind wave height.

2.4.4 Potential Dam Failures

2.4.4.4 Water Level at CRN Site

Replace the fourth sentence of the last paragraph of ESPA SSAR Section 2.4.4.5 with the following:

There are no impacts to SC1 SSCs at the CRN Site.

2.4.4.5 Coincident Wind Wave

Replace the fifth sentence of ESPA SSAR Section 2.4.4.5 with the following:

The effective fetch found for the CRN Site from available GIS terrain data was 4.25 mi, based on the site grade elevation of 814.5 ft NAVD88, which results in the critical site fetch length (Figure 2.4.3-16).

Replace the eighth sentence of ESPA SSAR Section 2.4.4.5 with the following:

CRN Site grade is 814.5 ft NAVD88 (814.9 ft NGVD29), 8.9 ft higher than the maximum calculated water surface elevation with wind wave height.

2.4.4.6 Erosions and Deposition Effects

Replace the last sentence of ESPA SSAR Section 2.4.4.6 with the following:

This less than two foot rise in Watts Bar Reservoir is far short of the nearly 18.5 ft of elevation rise needed based on the bounding PMF results to reach preliminary CRN plant grade.

2.4.4.7 Erosions and Deposition Effects

Replace the last sentence of ESPA SSAR Section 2.4.4.7 with the following:

This less than two foot rise in Watts Bar Reservoir is far short of the nearly 18.5 ft of elevation rise needed based on the bounding PMF results to reach preliminary CRN plant grade.

2.4.5 Probable Maximum Surge and Seiche Flooding

Replace the second sentence of the first paragraph of ESPA SSAR Section 2.4.5 with the following:

[

]

2.4.6 Probable Maximum Tsunami Hazards

Replace the second sentence of the first paragraph of ESPA SSAR Section 2.4.6 with the following:

In addition, the site finish grade elevation is at 814.5 ft NAVD88 (814.9 ft NGVD29).

2.4.7 Ice Effects

Replace the first paragraph of ESPA SSAR Section 2.4.7 with the following:

The potential impact of ice effects on the CRN Site is evaluated in this section. Because the site is located in a region of continental, humid subtropical climate, extreme ice conditions with potential adverse effects on SC1 SSCs are not typically present. Additionally, the BWRX-300 SMR does not rely on an external, SC1 water source and therefore will not be affected by any potential loss of water supply due to ice conditions in the region.

2.4.7.2 High and Low Water Levels

Replace the first paragraph of ESPA SSAR Section 2.4.7.2 with the following:

[

]

Replace the last paragraph of ESPA SSAR Section 2.4.7.2 with the following:

Low water conditions resulting from ice formation or accumulations that may cause interruption of stream flow in Clinch River arm of the Watts Bar Reservoir will not impact the site, as BWRX-300 SMR does not rely on an external water source for an SC1 water supply.

2.4.7.3 Ice Sheet Formation

Replace the first paragraph of ESPA SSAR Section 2.4.7.3 with the following:

The BWRX-300 SMR does not require external water sources for SC1 SSCs and does not rely on any open storage facilities or impoundments to supply or maintain the inventory for SC1 water use. Consequently, a reduction of stream flow in the river or storage volume in an impoundment due to ice sheet formation will not introduce any adverse impacts to SC1 SSCs.

Replace the first sentence of the second paragraph of ESPA SSAR Section 2.4.7.3 with the following:

The BWRX-300 SMR uses cooling towers to dissipate the excess heat load from the main steam condensers.

Replace the second sentence of the third paragraph of ESPA SSAR Section 2.4.7.3 with the following:

The ice layer thickness was estimated to evaluate the impact of ice formation on the cooling tower basins and intake structure.

2.4.7.4 Ice-Induced Forces and Blockages

Replace ESPA SSAR Section 2.4.7.4 with the following:

The BWRX-300 SMR does not include SC1 SSCs that are subject to ice-induced forces or blockages from either sheet ice or frazil ice.

2.4.7.7 Conclusion

Replace ESPA SSAR Section 2.4.7.7 with the following:

Historical and postulated ice conditions applicable to the CRN Site are evaluated to determine the impact on the safety of the plant. Due to the relatively mild climatic condition at the CRN Site, and the elevated design plant grade above natural drainages, in combination with the BWRX-300 SMR plant design that does not rely on external water sources for SC1 water use, it is concluded that ice effects will not cause flooding or water availability concerns for the SC1 SSCs.

2.4.8 Cooling Water Canals and Reservoirs

Replace ESPA SSAR Section 2.4.8 with the following:

The BWRX-300 SMR plant design does not rely on the Clinch River arm of the Watts Bar Reservoir for an SC1 water supply, and the CRN Site does not include cooling water canals or

reservoirs. The CRN Site uses the Clinch River arm of the Watts Bar Reservoir as the source of makeup water for normal plant cooling.

2.4.9 Channel Diversions

Replace ESPA SSAR Section 2.4.9 with the following:

This section describes the effects of channel diversions as potential hazards to the BWRX-300 SMR. Based on the review of hydrologic, hydraulic, climatic, topographic and geologic evidence and anthropogenic impacts near the CRN Site, as described below, channel diversions are not expected to cause flooding hazards at the site. Additionally, the BWRX-300 SMR does not require SC1 water supply from the Clinch River arm of the Watts Bar Reservoir. Consequently, the safety of the plant will not be compromised due to a loss of water supply even in the highly unlikely event of a channel diversion near the site.

2.4.9.6 Alternative Water Sources

Replace the first paragraph of ESPA SSAR Section 2.4.9.6 with the following:

The BWRX-300 SMR does not rely on the Clinch River arm of the Watts Bar Reservoir for SC1 water use. However, it is the source for the cooling tower makeup water for the normal heat sink with the water intake located on the river. The makeup water intake, while unlikely to be affected by channel diversions under normal operation conditions, could be subject to impacts from shoreline erosion. As described previously, the shoreline erosion processes would occur at a localized scale and at a rate that could be mitigated. In the unlikely event that a channel diversion occurs (due to, for example, dam break and slope failure) interrupting the makeup water supply, the plant can still be safely shutdown. Plant water use is further described in Subsection 2.4.11.

2.4.9.8 Conclusions

Replace the second sentence of the first paragraph of ESPA SSAR Section 2.4.9.8 with the following:

Moreover, in the unlikely event that channel diversions occur, there will be no impact to SC1 SSCs at the CRN Site.

2.4.10 Flooding Protection Requirements

Replace the first sentence of the first paragraph of ESPA SSAR Section 2.4.10 with the following:

[

]

*[

]

2.4.11 Low Water Considerations

Replace the first and second sentences of the first paragraph of ESPA SSAR Section 2.4.11 with the following:

The Clinch River Nuclear (CRN) Site does not rely on the Clinch River arm of the Watts Bar Reservoir to support SC1 SSCs, including the ultimate heat sink that provides emergency cooling water. However, the Clinch River arm of the Watts Bar Reservoir would be used as a water source for non-SC1 SSCs, primarily the normal cooling system and water processing plant that feeds the demineralized water users and liquid radwaste treatment system.

Replace the first sentence of the second paragraph of ESPA SSAR Section 2.4.11 with the following:

The CRN Site is located on the Clinch River arm of the Watts Bar Reservoir between River Mile 14.5 and River Mile 19, and the surface water demand on the reservoir would be supplied using a pump intake structure located at Clinch River Mile 17.9, approximately 5.2 river miles downstream from Melton Hill Dam.

2.4.11.1.1 Flow Release from Melton Hill Dam

Replace the first two sentences of the first paragraph of the Reservoir Storage section of ESPA SSAR Section 2.4.11.1.1 with the following:

To evaluate the surface water availability for CRN Site water demand, the depletion rate of the reservoir storage below the winter/normal minimum operating pool level was estimated using the stage-storage rating curve of Watts Bar Reservoir in conjunction with conservative assumptions on the expected water demands, reservoir inflows and outflows.

Replace the fifth sentence of the second paragraph of ESPA SSAR Section 2.4.11.1.1 with the following:

In addition, the average weekly discharge from Melton Hill Reservoir over the long term is about 4800 cfs, with a maximum weekly discharge of about 25,450 cfs, much higher than the projected water demand (consumptive surface water use) of 28.5 cfs from the CRN Site.

Replace the first sentence of the third paragraph of the Reservoir Storage section of ESPA SSAR Section 2.4.11.1.1 with the following:

It can be concluded from the above assessment that the amount of storage volume available in Watts Bar Reservoir, even during the worst drought condition when hypothetically the only inflow to the Reservoir is the minimum release from Melton Hill Dam, can conservatively sustain the continuous withdrawal of surface water to meet the water demands of the CRN Site for extended periods of time, in addition to the continuous supply to other water users.

2.4.11.2 Low Water Resulting from Surges, Seiches, or Tsunamis

Replace the first and second sentences of the first paragraph of ESPA SSAR Section 2.4.11.2 with the following:

There is no safety impact on the CRN Site due to low water conditions generated by any mechanism because the plant does not rely on the Clinch River arm of the Watts Bar Reservoir for its SC1 water use. The non-SC1 water supply is also not expected to be affected normally by low water conditions resulting from surges, seiches, tsunamis or other external events.

Replace the second sentence of the second paragraph of ESPA SSAR Section 2.4.11.2 with the following:

However, no SC1 SSCs at the CRN Site would be impacted.

Replace the third paragraph of ESPA SSAR Section 2.4.11.2 with the following:

Similarly, the unlikely failures of the Watts Bar Dam and Melton Hill Dam would potentially create a low water condition at the CRN Site, but there would be no SC1 impacts.

2.4.11.4 Future Controls

Replace the first and second sentences of the first paragraph of ESPA SSAR Section 2.4.11.4 with the following:

The CRN Site does not rely upon the Clinch River arm of the Watts Bar Reservoir for SC1 water use and therefore there would not be any safety impact as a result of future uses or controls in the Reservoir. For normal water use, the storage capacity of Watts Bar Reservoir is adequate to sustain the continuous supply of surface water to meet the needs of the CRN Site through a drought event equivalent to the drought of record as discussed in Subsection 2.4.11.3.

2.4.12 Groundwater

Replace the first sentence of the second paragraph of ESPA SSAR Section 2.4.12 with the following:

Regional and local groundwater resources that could be affected by the construction and operation of the BWRX-300 SMR are described below.

2.4.12.1.1 Physiography and Geomorphology

Replace the last sentence of the third paragraph of ESPA SSAR Section 2.4.12.1.1 with the following:

Plant grade is at approximately 814.5 ft, placing the BWRX-300 SMR about 74.5 ft above the water level of the river.

Replace Figure 2.4.12-4 with Figure 2.4.12-4R in the first and last sentence of the eighth paragraph of ESPA SSAR Section 2.4.12.1.1.

Replace Figure 2.4.12-5 with Figure 2.4.12-5R in the second sentence of the eighth paragraph of ESPA SSAR Section 2.4.12.1.1.

2.4.12.1.4.1 CRBRP Investigation

Insert the following after the first paragraph in ESPA SSAR Section 2.4.12.1.4.1:

TVA identified no abandoned wells in the area adjacent to the CRBRP excavation while performing the well drilling associated with the CRN Site subsurface investigation and based on the information on well locations for the CRBRP, it is likely that the wells were destroyed and/or removed when the excavation and subsequent site redress for the CRBRP was performed.

Replace the first sentence of the fifth paragraph of ESPA SSAR Section 2.4.12.1.4.1 with the following:

Water level measurements on the CRN Site indicated as much as a 25 ft fluctuation in water levels.

Delete the sixth paragraph of ESPA SSAR Section 2.4.12.1.4.1

2.4.12.1.4.2 CRN Site Investigation

Replace the fourth sentence of the second paragraph of ESPA SSAR Section 2.4.12.1.4.2 with the following:

Due to the naturally occurring hydrocarbon in OW-422L, this well cluster (OW-422 U, L and D) was not developed and since then fully grouted.

Replace Figure 2.4.12-4 with Figure 2.4.12-4R in the fifth sentence of the first paragraph of ESPA SSAR Section 2.4.12.1.4.2.

2.4.12.2.1.3 Projected Groundwater Use

Replace the first sentence of the second paragraph of ESPA SSAR Section 2.4.12.2.1.3 with the following:

The BWRX-300 SMR does not require groundwater as a source for cooling water, potable water, or other plant needs.

2.4.12.2.1.4 CRN Site Groundwater Use Summary

Replace the last paragraph of ESPA SSAR Section 2.4.12.2.1.4 with the following:

The BWRX-300 SMR does not rely on groundwater for any part of its operating supply. Thus, there is no groundwater demand due to the BWRX-300 SMR. There are no active groundwater current or projected users for the CRN Site.

2.4.12.2.2 Groundwater Flow Directions

Replace the fourth sentence of the third paragraph of ESPA SSAR Section 2.4.12.2.2 with the following:

Figure 2.4.12-19R through Figure 2.4.12-28R present the potentiometric surface maps.

Replace the eleventh sentence of the third paragraph of ESPA SSAR Section 2.4.12.2.2 with the following:

This is derived based on a shortest distance of 1200 ft from the reactor locations to the edge of the Clinch River arm of the Watts Bar Reservoir; lowest stage of the reservoir at 735 ft NAVD88 (during the monitoring period); and the maximum water levels at OW-101U and OW-202U of 798.99 and 800.30 ft NAVD88.

2.4.12.2.4.1 Hydrogeological Properties

Replace Figure 2.4.12-4 with Figure 2.4.12-4R in second sentence of the first paragraph of the Aquifer Pumping Test subsection.

2.4.12.3.2 Advective Transport

Replace the last paragraph of ESPA SSAR Section 2.4.12.3.2 with the following:

Table 2.4.12-17R presents a summary of these parameters and the linear velocity and travel times determined from these parameters. Using the representative parameter values, a travel time of 308 days is determined (Table 2.4.12-17R).

2.4.12.5.1 Groundwater Flow Model

Replace Figure 2.4.12-40 with Figure 2.4.12-40R in the second sentence of the second paragraph of ESPA SSAR Section 2.4.12.5.1.

Replace the fifth paragraph of ESPA SSAR Section 2.4.12.5.1 with the following:

Post-construction modeling is performed to estimate the response of groundwater levels to the inclusion of the following BWRX-300 specific structures in the model: radwaste building, reactor building, and turbine building. A single BWRX-300 SMR developed by General Electric (GE) Hitachi is planned for the CRN Site and included as Unit 1 in the Construction Permit Application. The location of the Unit 1 reactor building, radwaste building, and turbine building coincide with the Profile C cross-sectional model. The embedment foundation depth of the reactor building is 129.5 feet below grade. The grade elevation at the power block area at the reactor building was assigned a value of 814.5 ft NAVD88. A uniform recharge of 8.76 in./yr was assigned in the post-construction models except at the power block area and part of the turbine area (which are comprised of paved areas and buildings). A construction fill hydraulic conductivity of 1.5 ft/day was assigned in the post-construction model. Modeling results indicate a maximum piezometric head underneath the reactor building of 814.5 ft NAVD88, which is the same as the power block plant site grade elevation. The maximum piezometric head underneath the turbine building foundation is estimated to be 814.2 ft NAVD88, which is 0.3 ft below the plant site grade elevation. The estimated maximum piezometric head of 814.5 ft NAVD88 meets the BWRX-300 generic groundwater heads (Reference 2.4.12-51) conservatively selected to be at plant grade.

2.4.12.5.2 Hydrostatic Loading

Replace Figure 2.4.12-41 with Figure 2.4.12-41R in the last paragraph of ESPA SSAR Section 2.4.12.5.2.

2.4.12.7 References

Add the following Reference to ESPA SSAR Section 2.4.12.7:

2.4.12-51 NEDO-33914-A, BWRX-300 Advanced Civil Construction and Design Approach, GE Hitachi Energy Nuclear, Revision 2, June 2022.

Replace Table 2.4.12-17 with the following:

Table 2.4.12-17R Groundwater Linear Velocity and Travel Time

Property	Representative Value	Source
Hydraulic Conductivity (ft/d)	2.6	Maximum calculated value as documented in Table 2.4.12-12 (observation well OW-423L)
Horizontal Hydraulic Gradient (ft/ft)	0.07	Mean value as presented in Table 2.4.12-8
Effective Porosity	0.0467	Mean value determined in Table 2.4.12-13, using the Immersion test method results which the referenced author identified as the test method that yields results that most accurately approaches the true effective porosity value.
Distance to Receptor (ft)	1200	Shortest distance from edge of power block area to Clinch River arm of the Watts Bar Reservoir (Figure 2.4.13-1R)

Calculated Values	
Linear Velocity (ft/d)	3.90
Travel Time (days)	308
Travel Time (years)	0.84

Replace Figure 2.4.12-4 with the following:

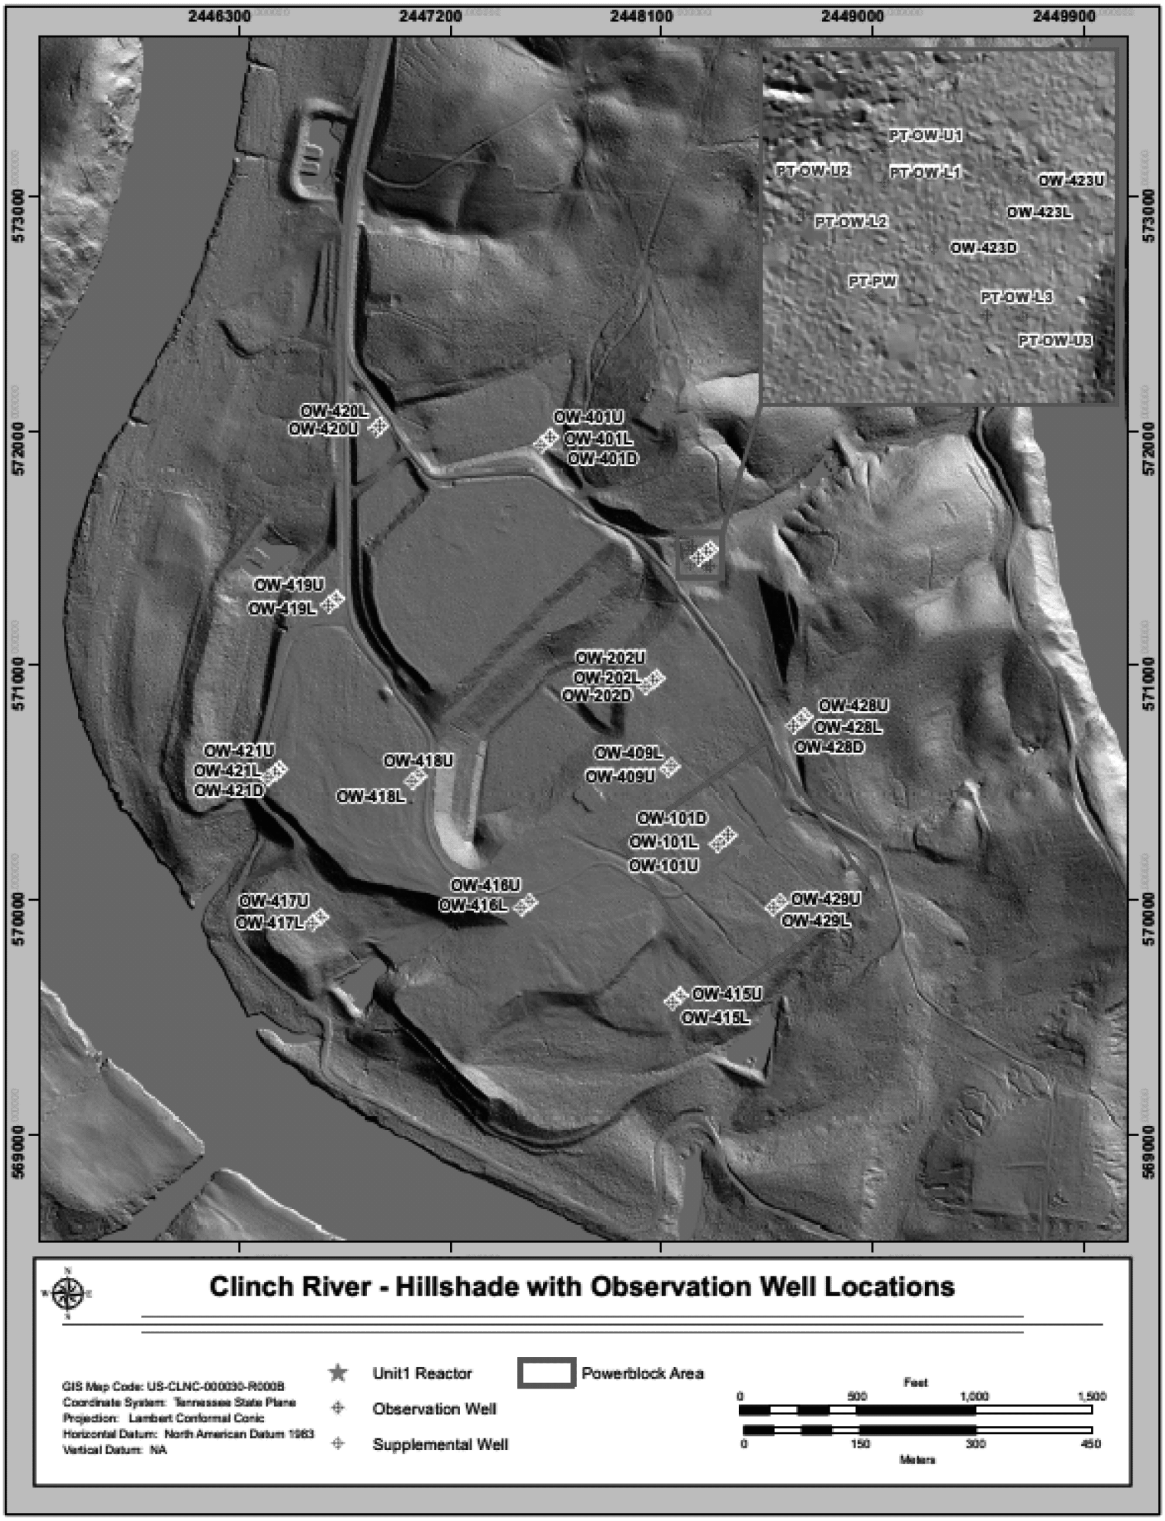

Figure 2.4.12-4R Current Site Topography and Observation Well Locations

Replace Figure 2.4.12-5 with the following:

Figure 2.4.12-5R Clinch River Breeder Reactor Project Fill and Excavation Areas

Replace Figure 2.4.12-19 with the following:

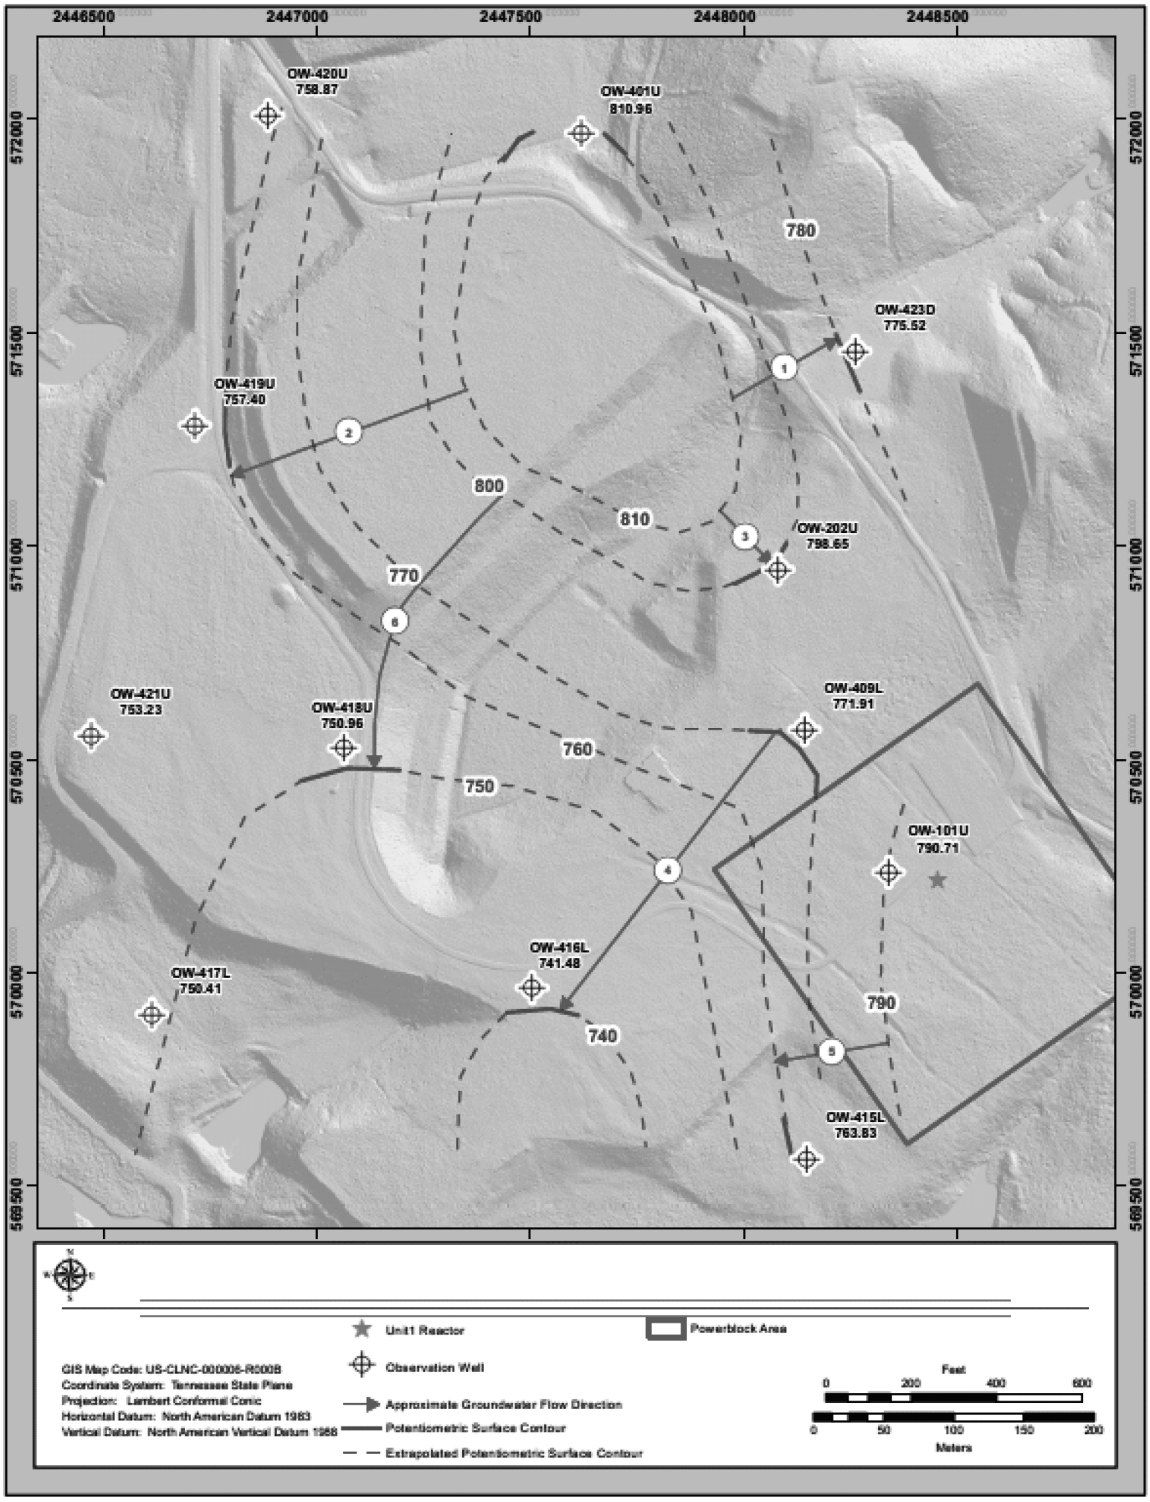

Figure 2.4.12-19R Potentiometric Surface Map for September 24, 2013

Replace Figure 2.4.12-20 with the following:

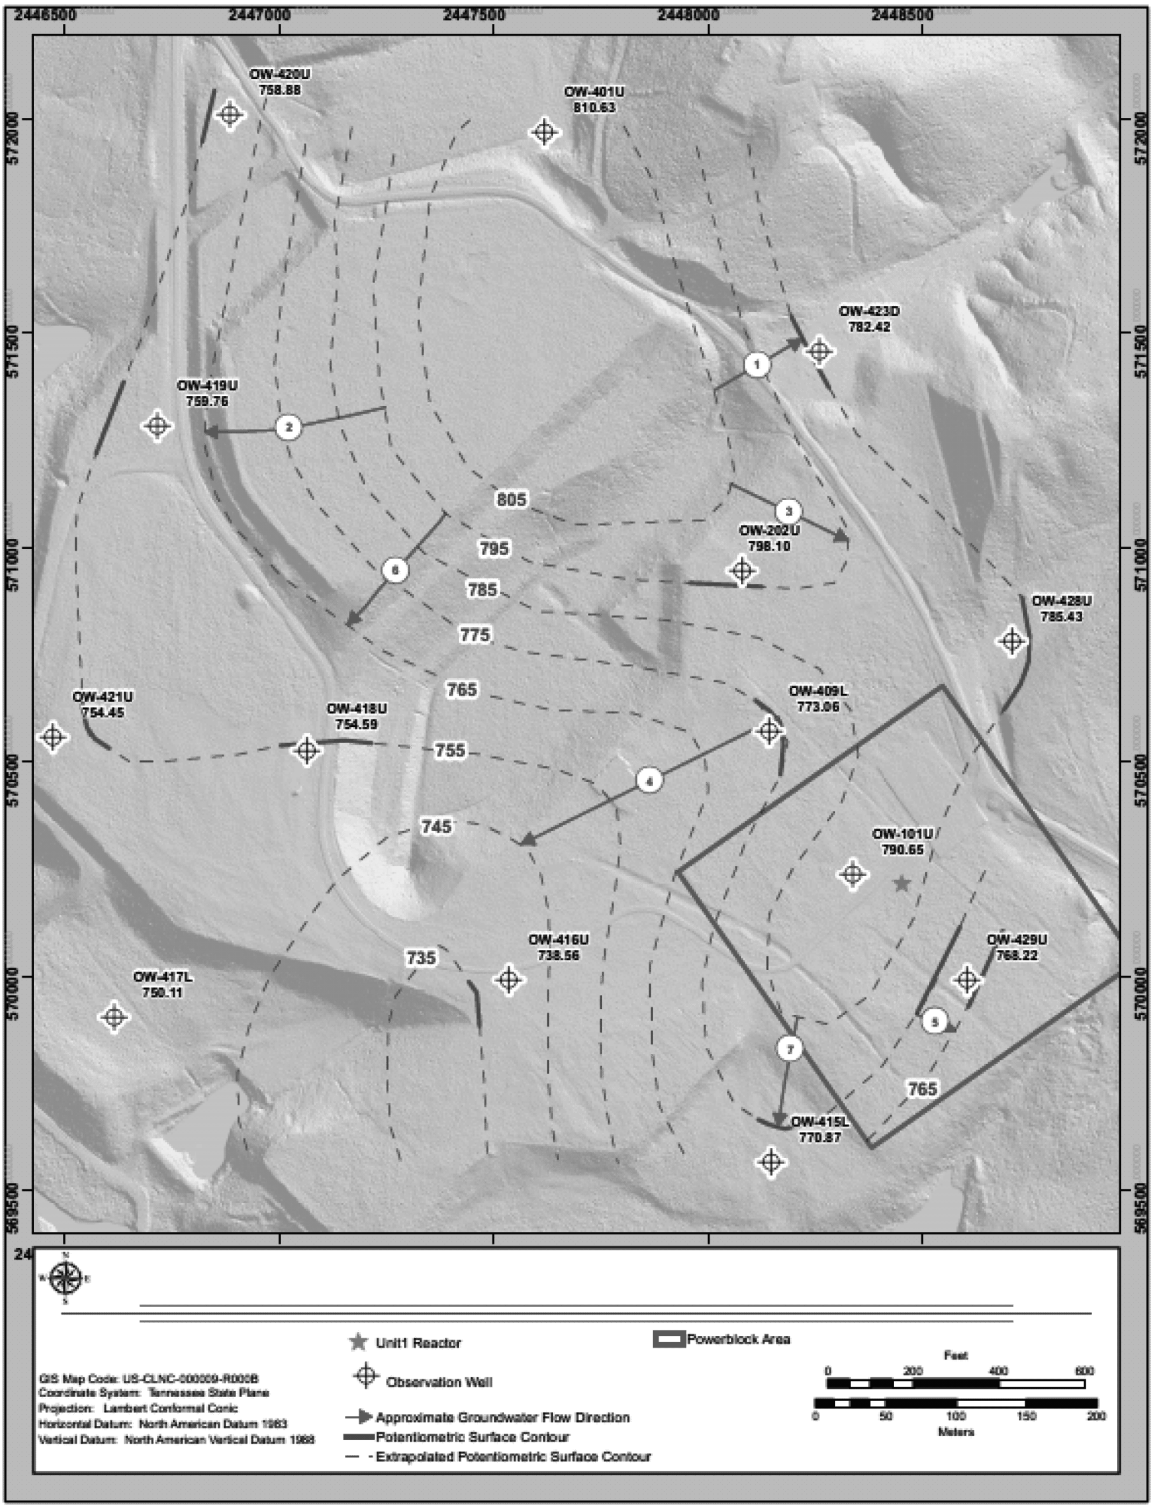

Figure 2.4.12-20R Potentiometric Surface Map for December 20, 2013

Replace Figure 2.4.12-21 with the following:

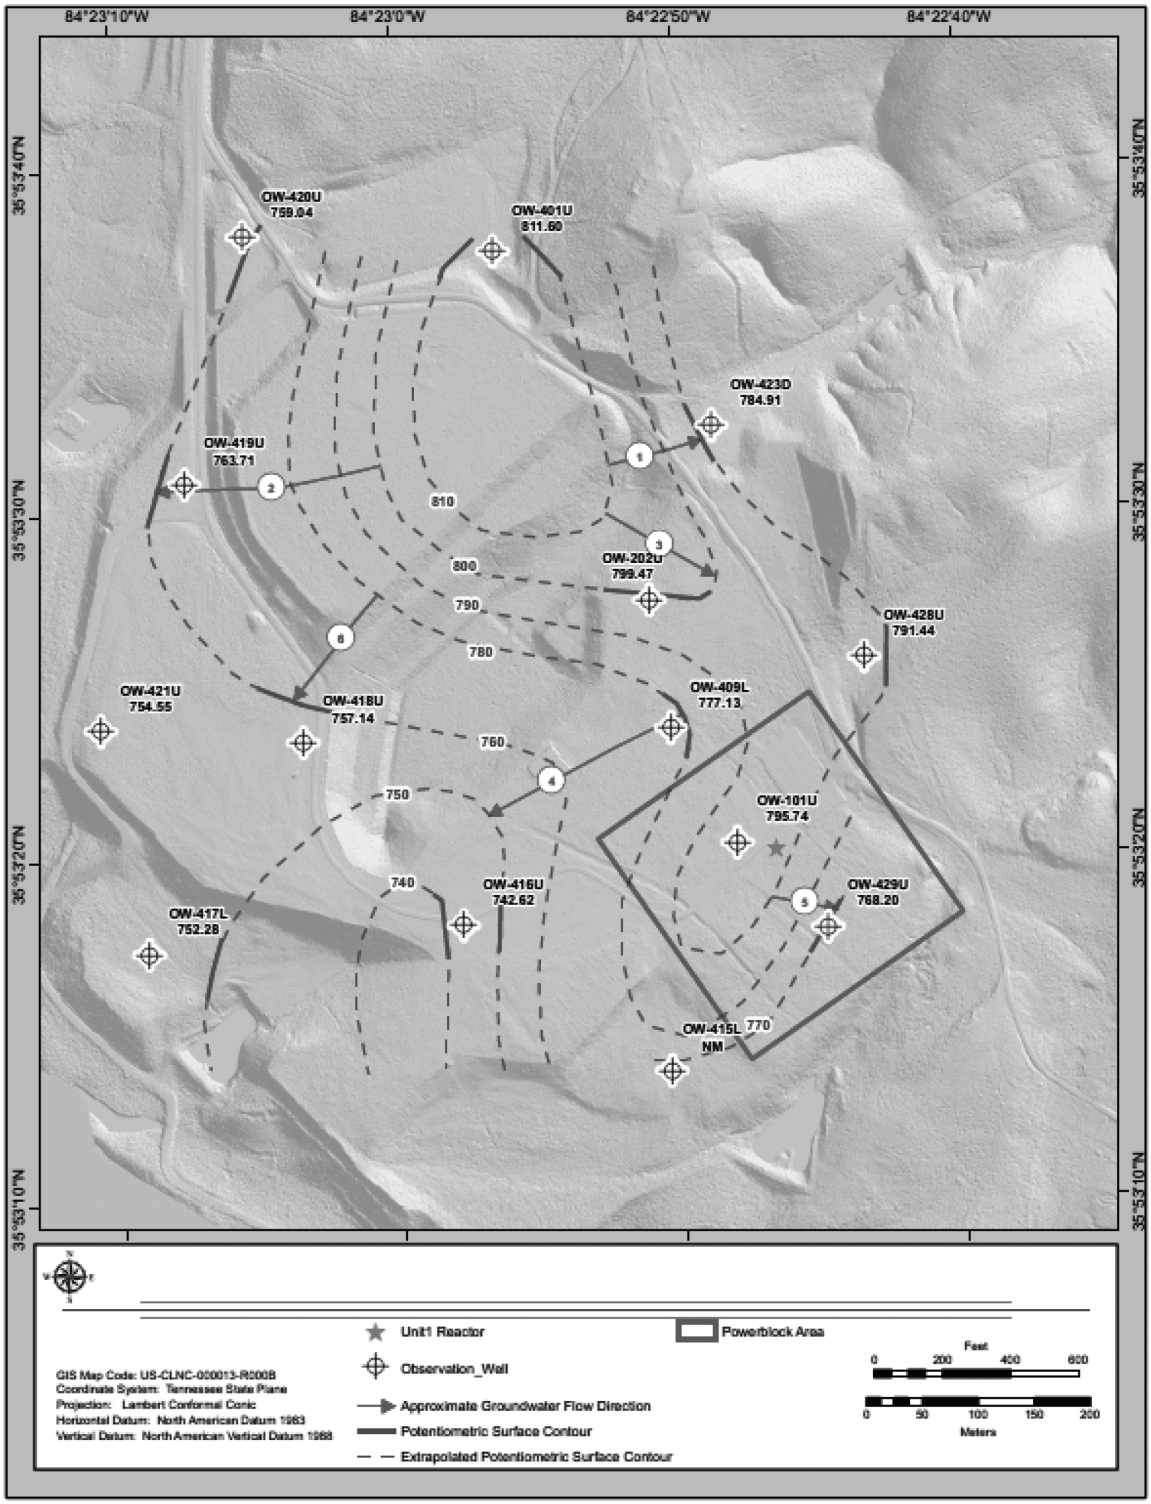

Figure 2.4.12-21R Potentiometric Surface Map for January 13, 2014

Replace Figure 2.4.12-22 with the following:

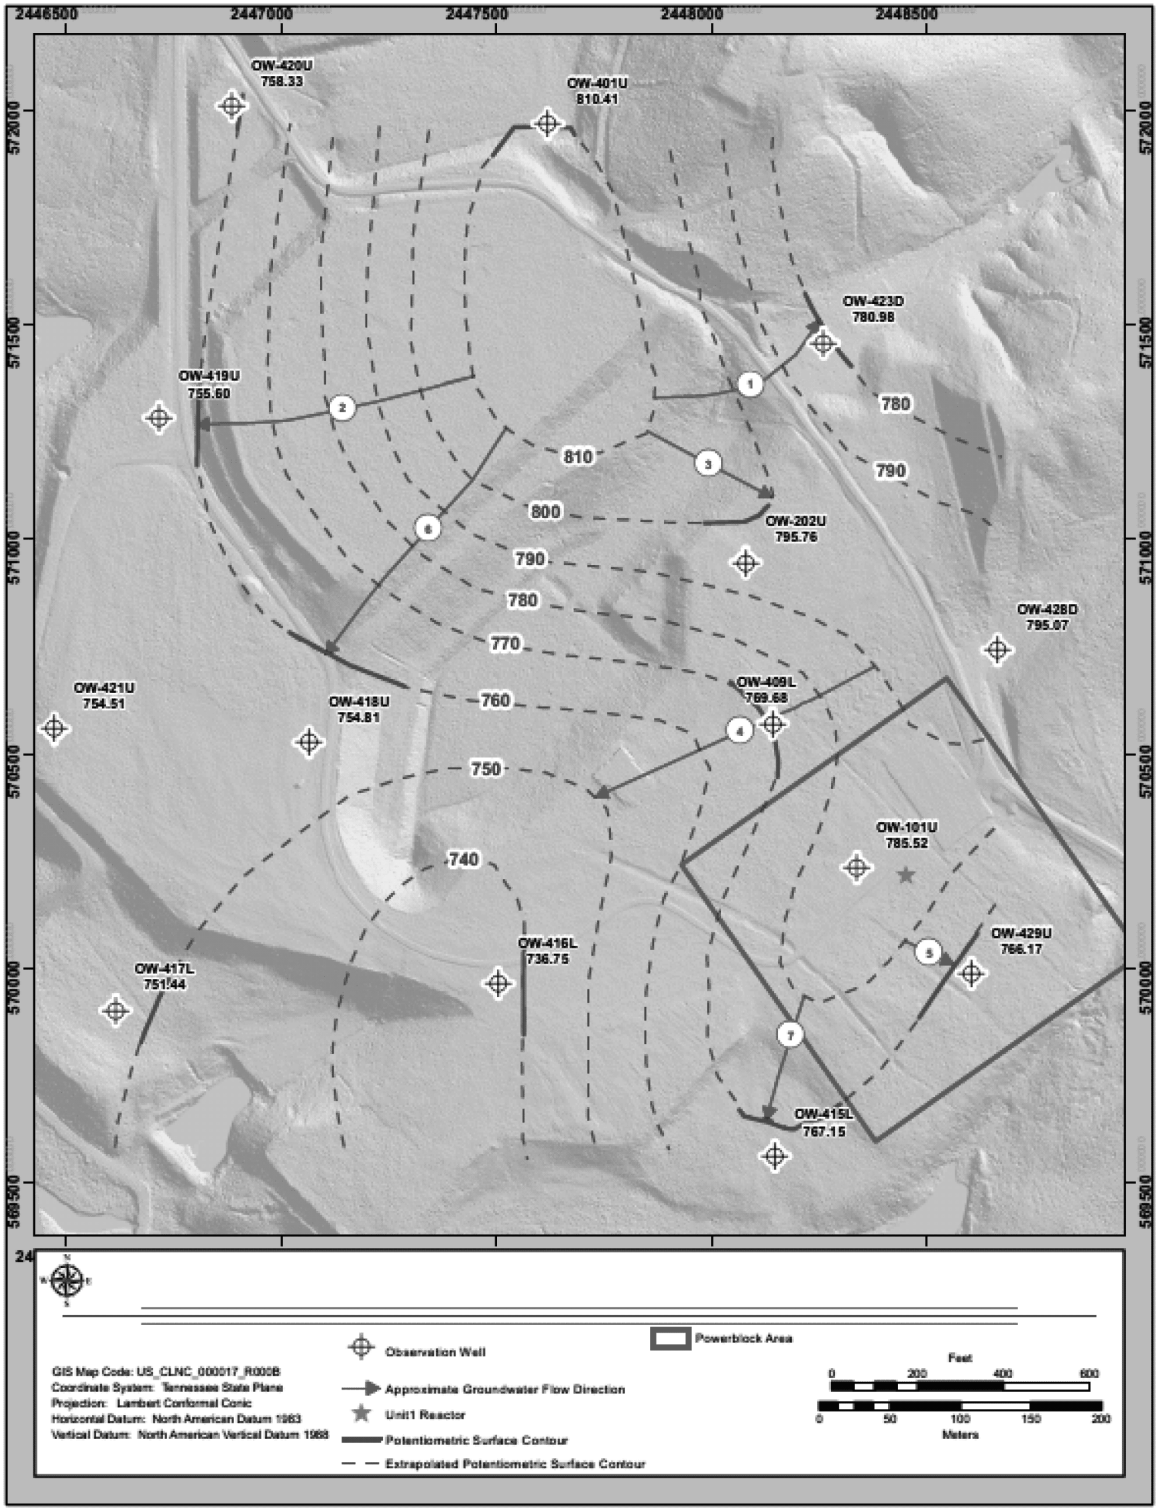

Figure 2.4.12-22R Potentiometric Surface Map for March 16, 2014

Replace Figure 2.4.12-23 with the following:

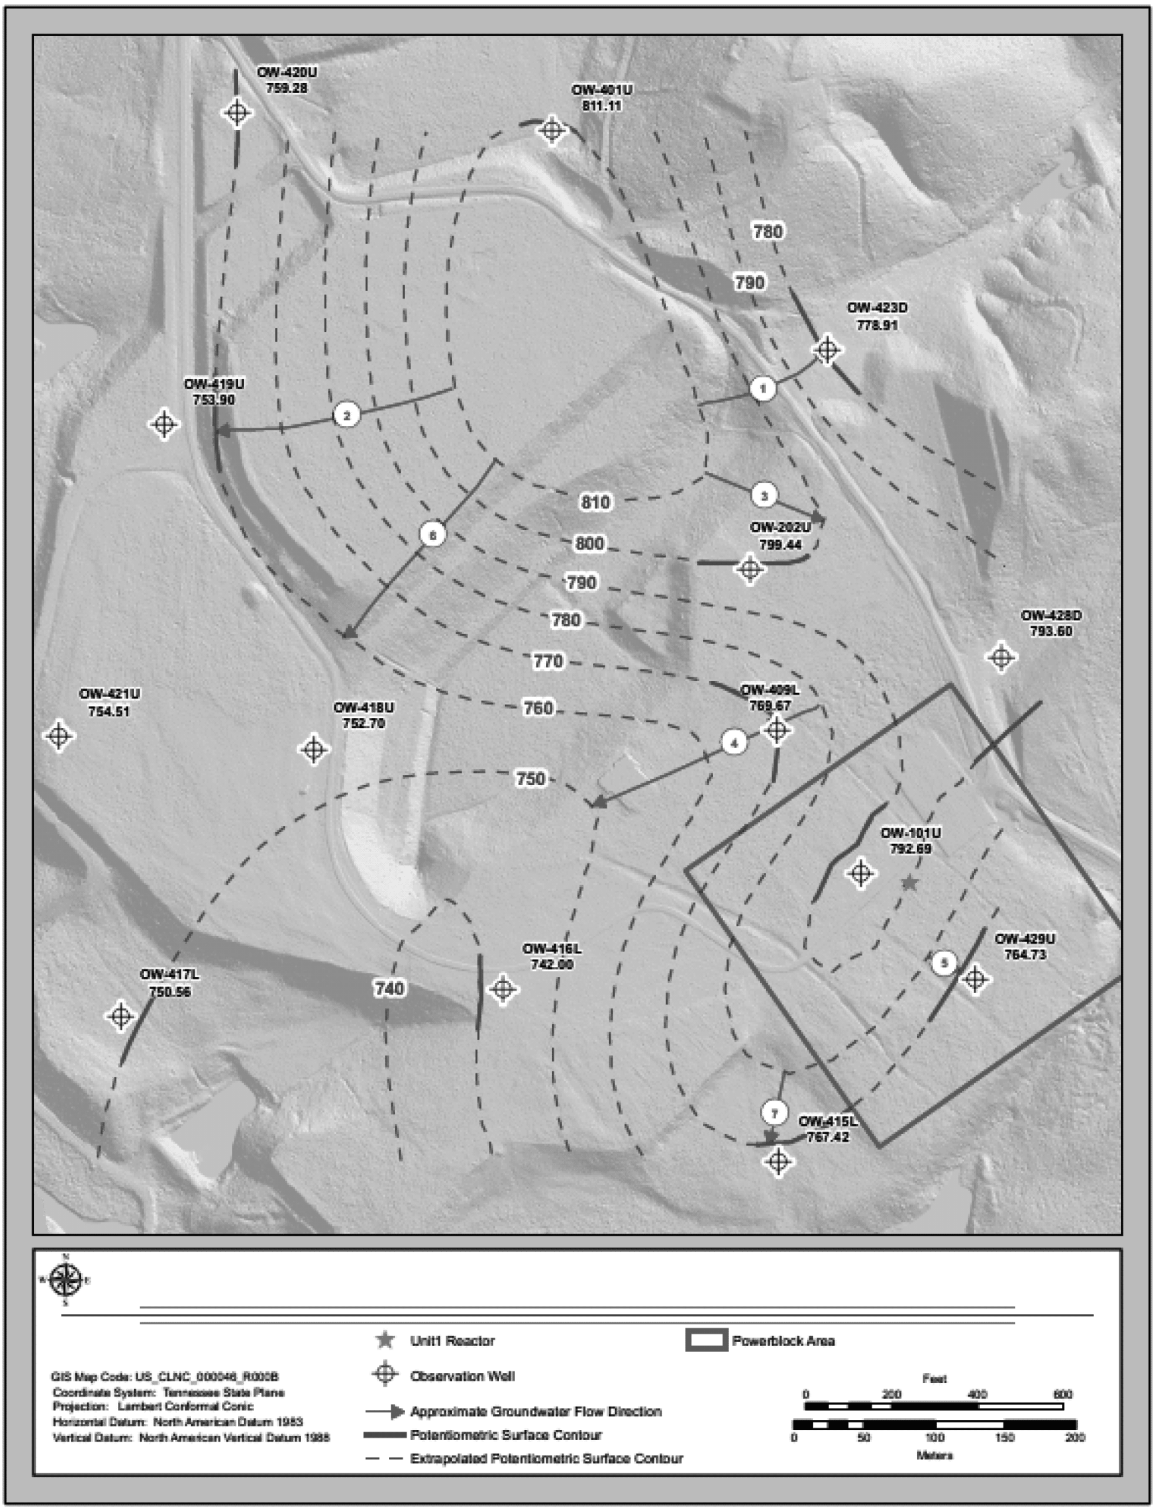

Figure 2.4.12-23R Potentiometric Surface Map for May 15, 2014

Replace Figure 2.4.12-24 with the following:

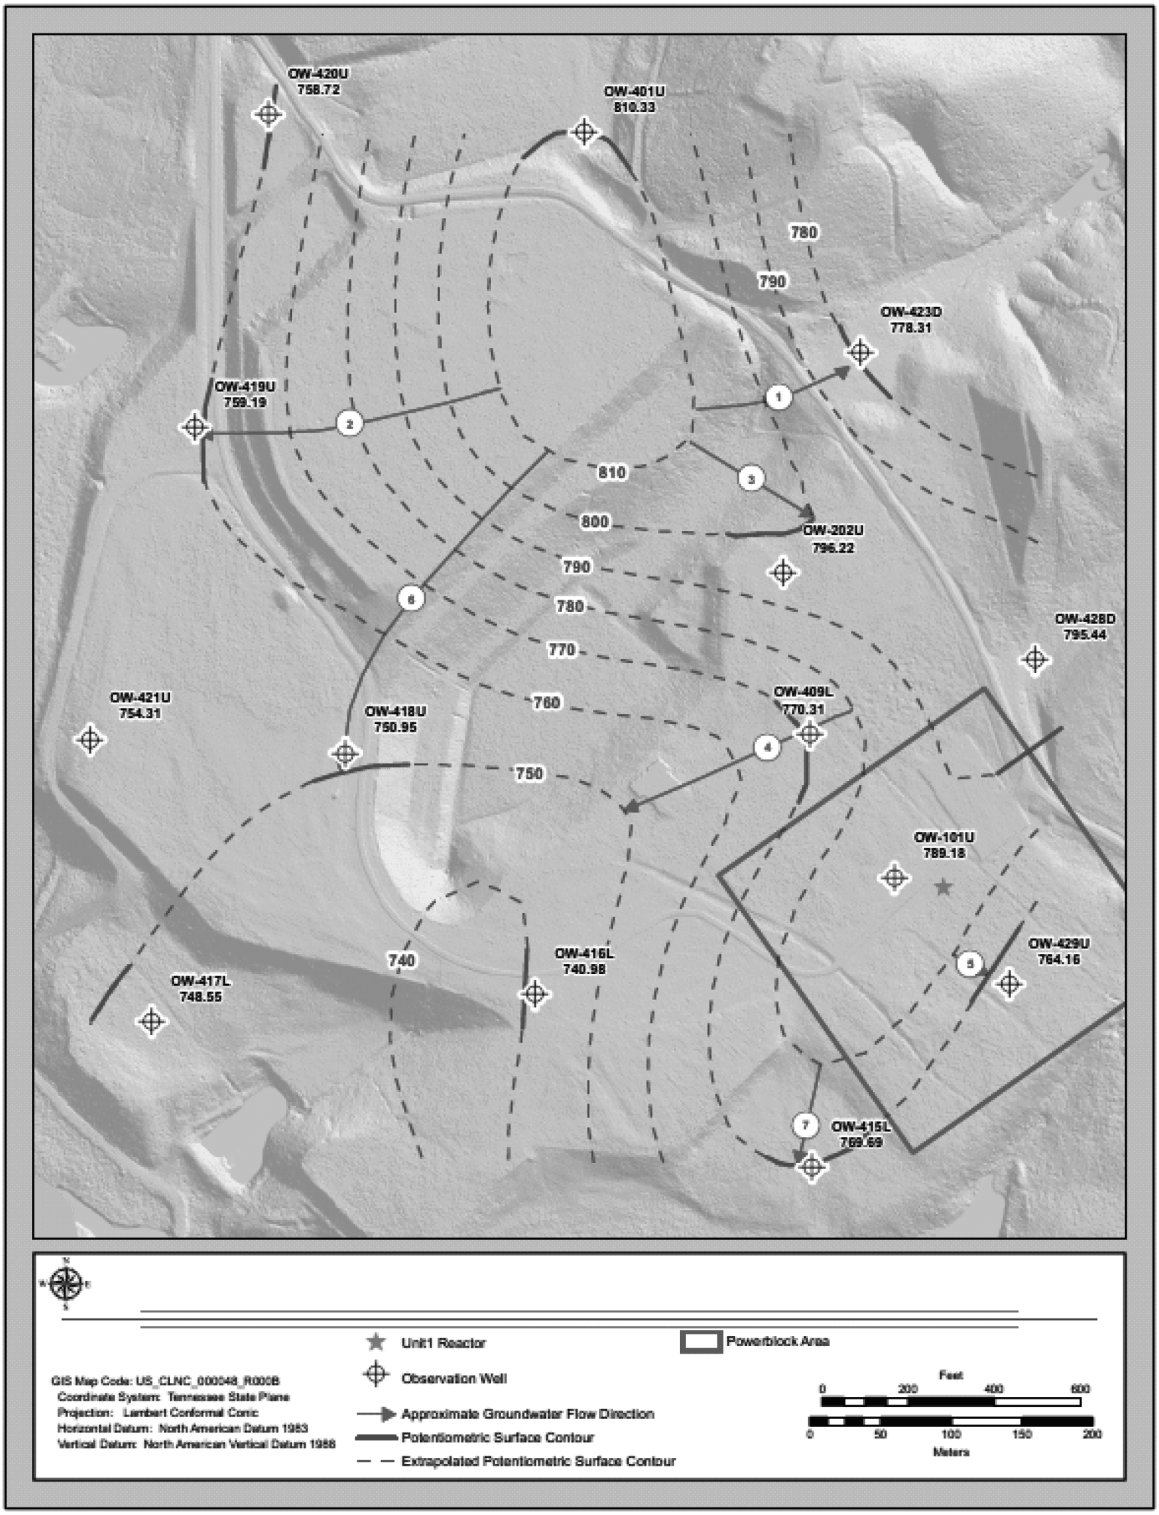

Figure 2.4.12-24R Potentiometric Surface Map for August 18, 2014

Replace Figure 2.4.12-25 with the following:

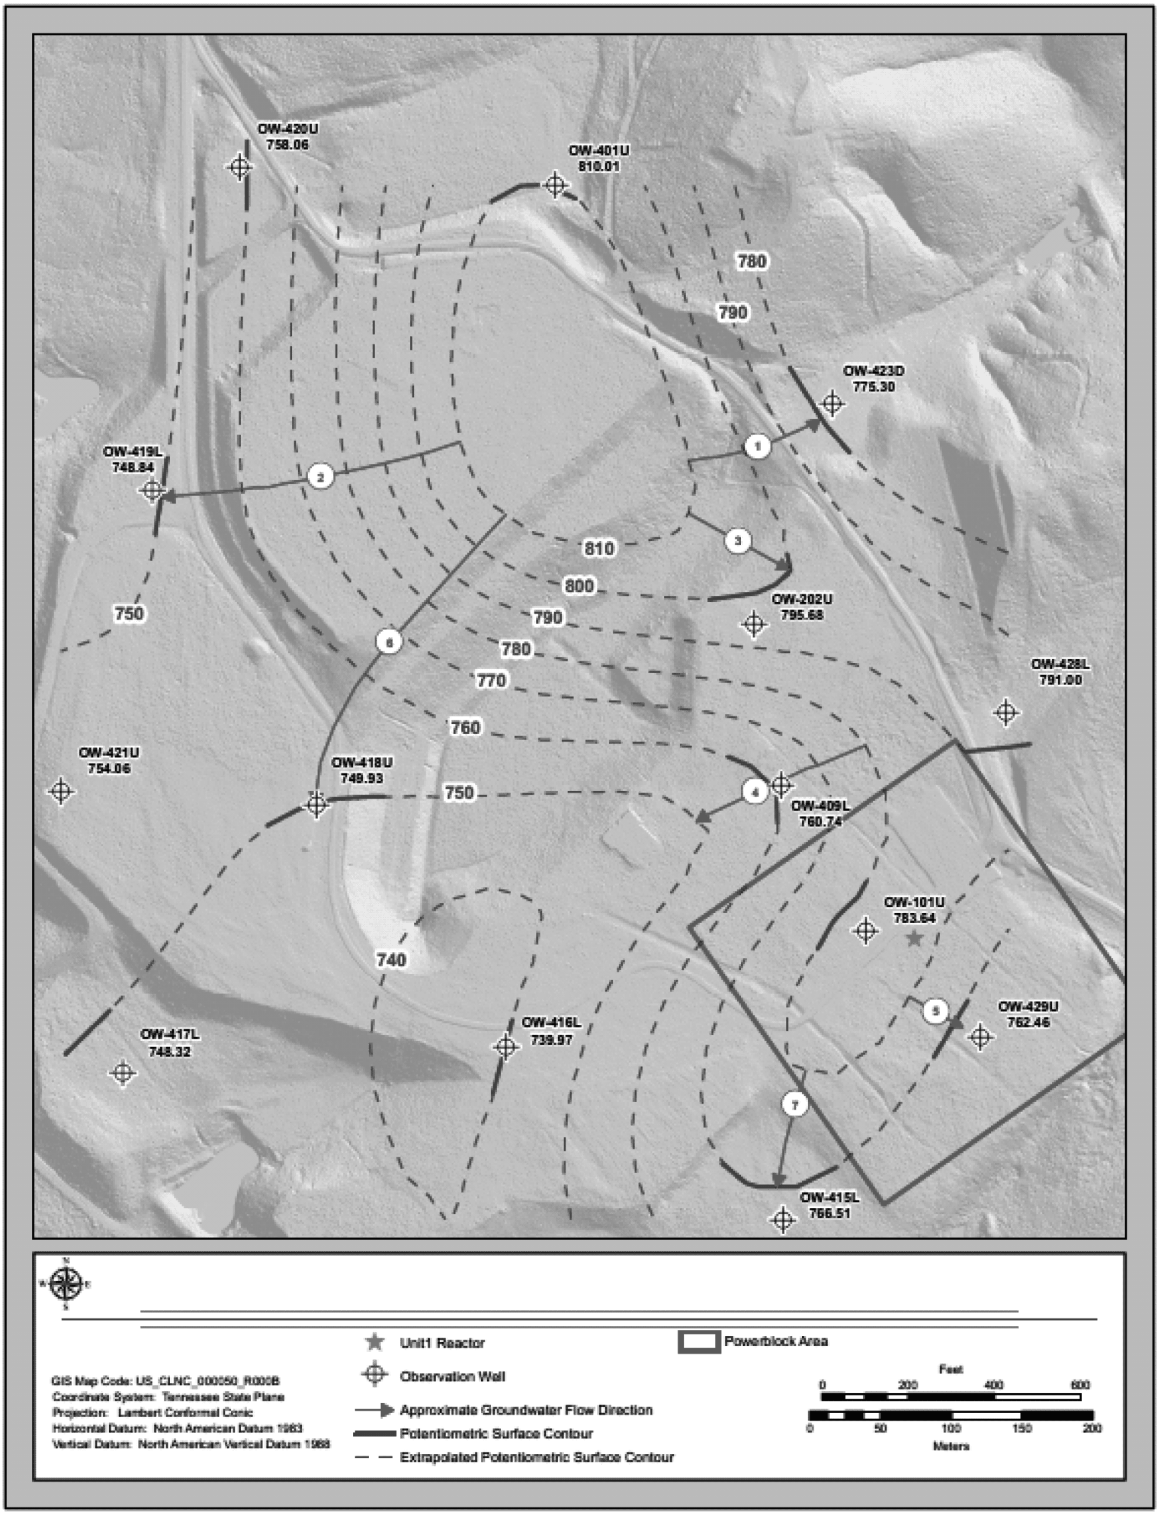

Figure 2.4.12-25R Potentiometric Surface Map for November 4, 2014

Replace Figure 2.4.12-26 with the following:

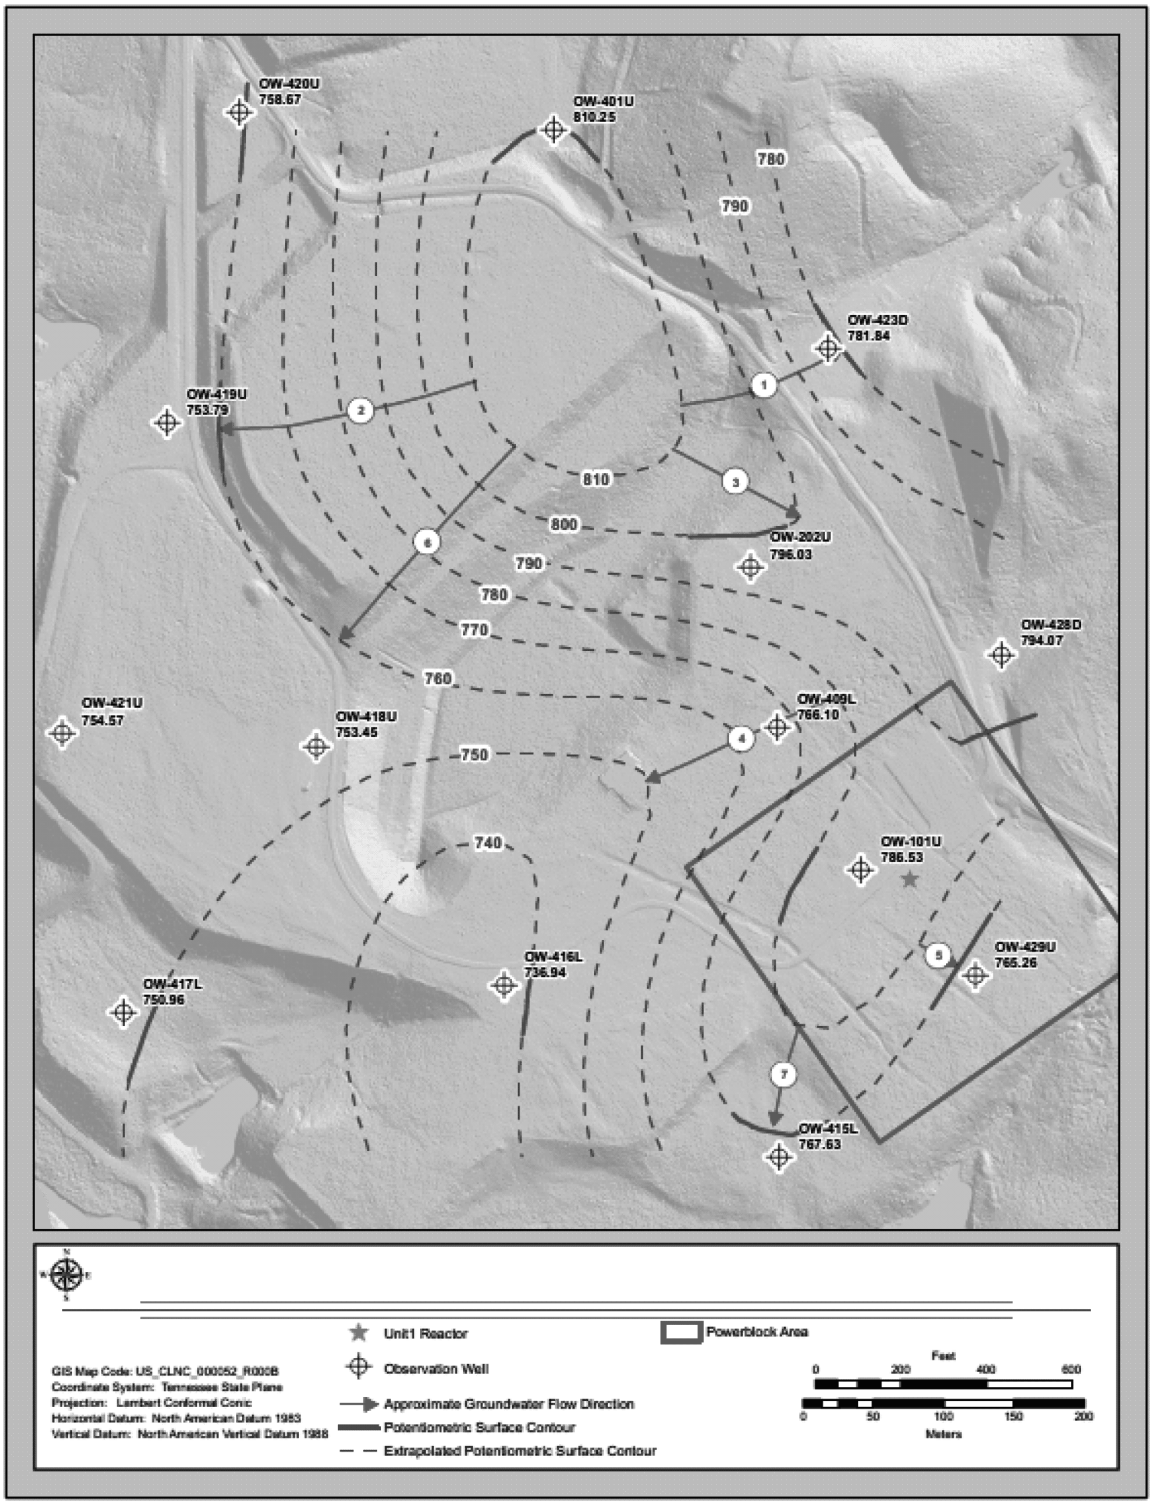

Figure 2.4.12-26R Potentiometric Surface Map for February 12, 2015

Replace Figure 2.4.12-27 with the following:

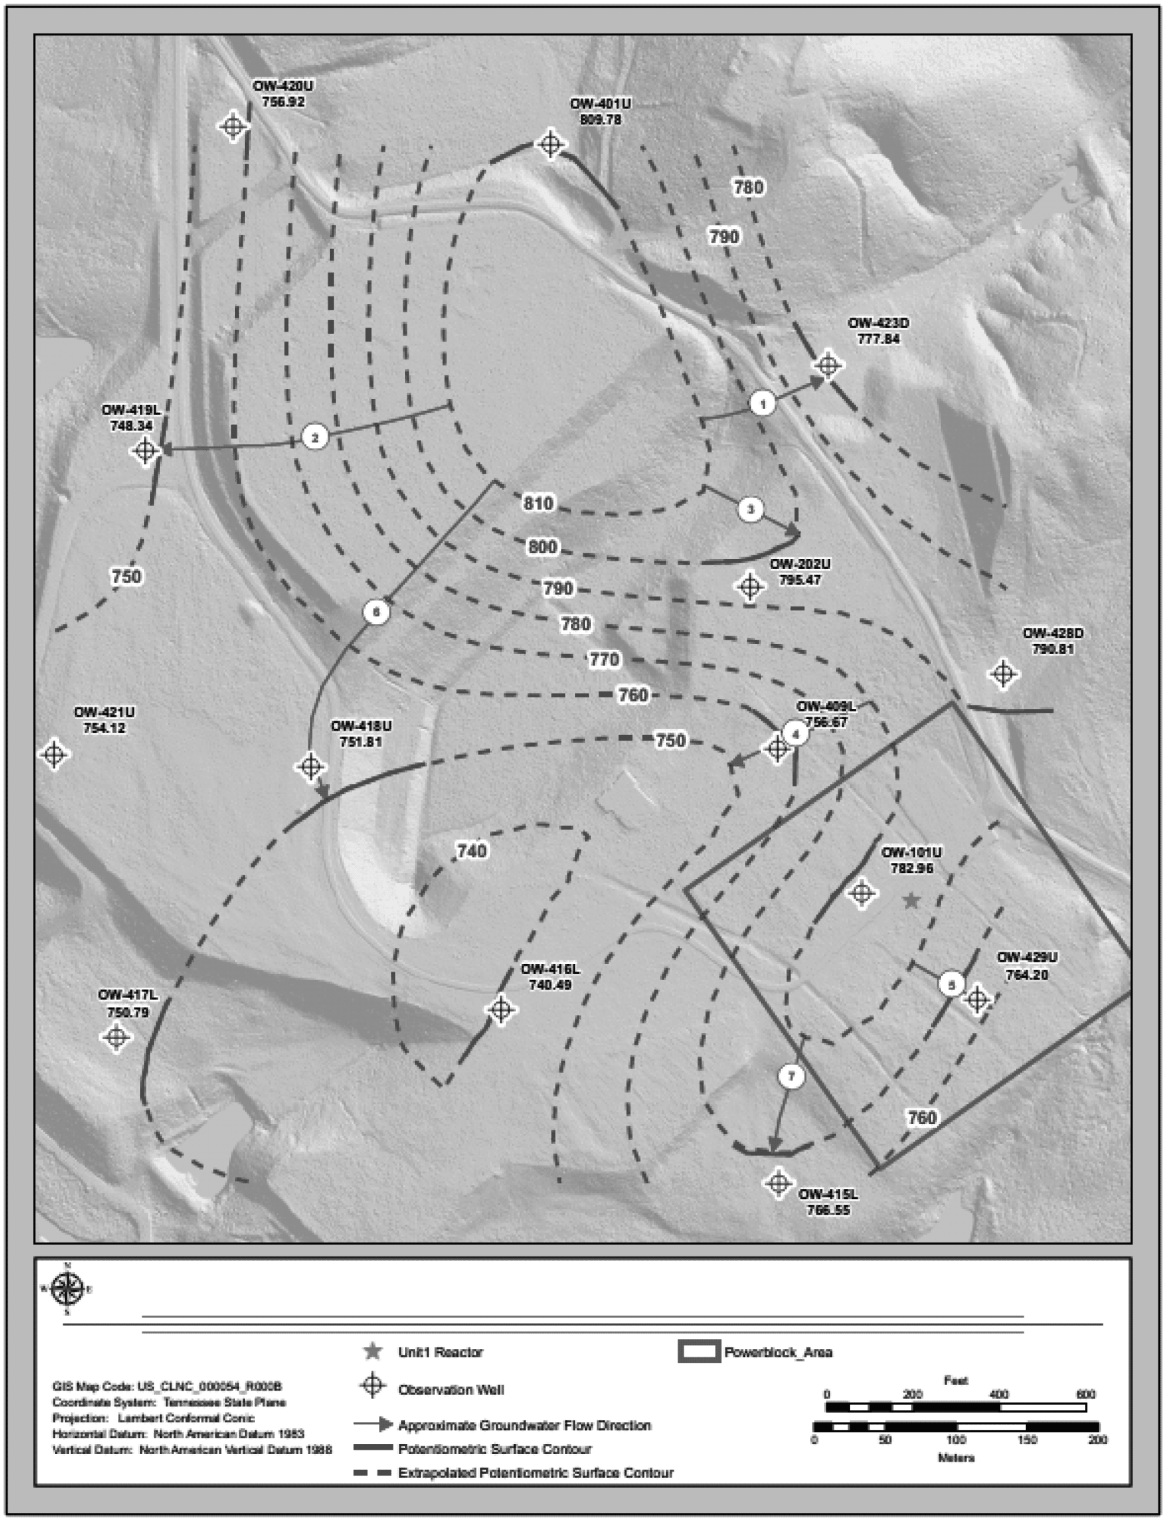

Figure 2.4.12-27R Potentiometric Surface Map for May 19, 2015

Replace Figure 2.4.12-28 with the following:

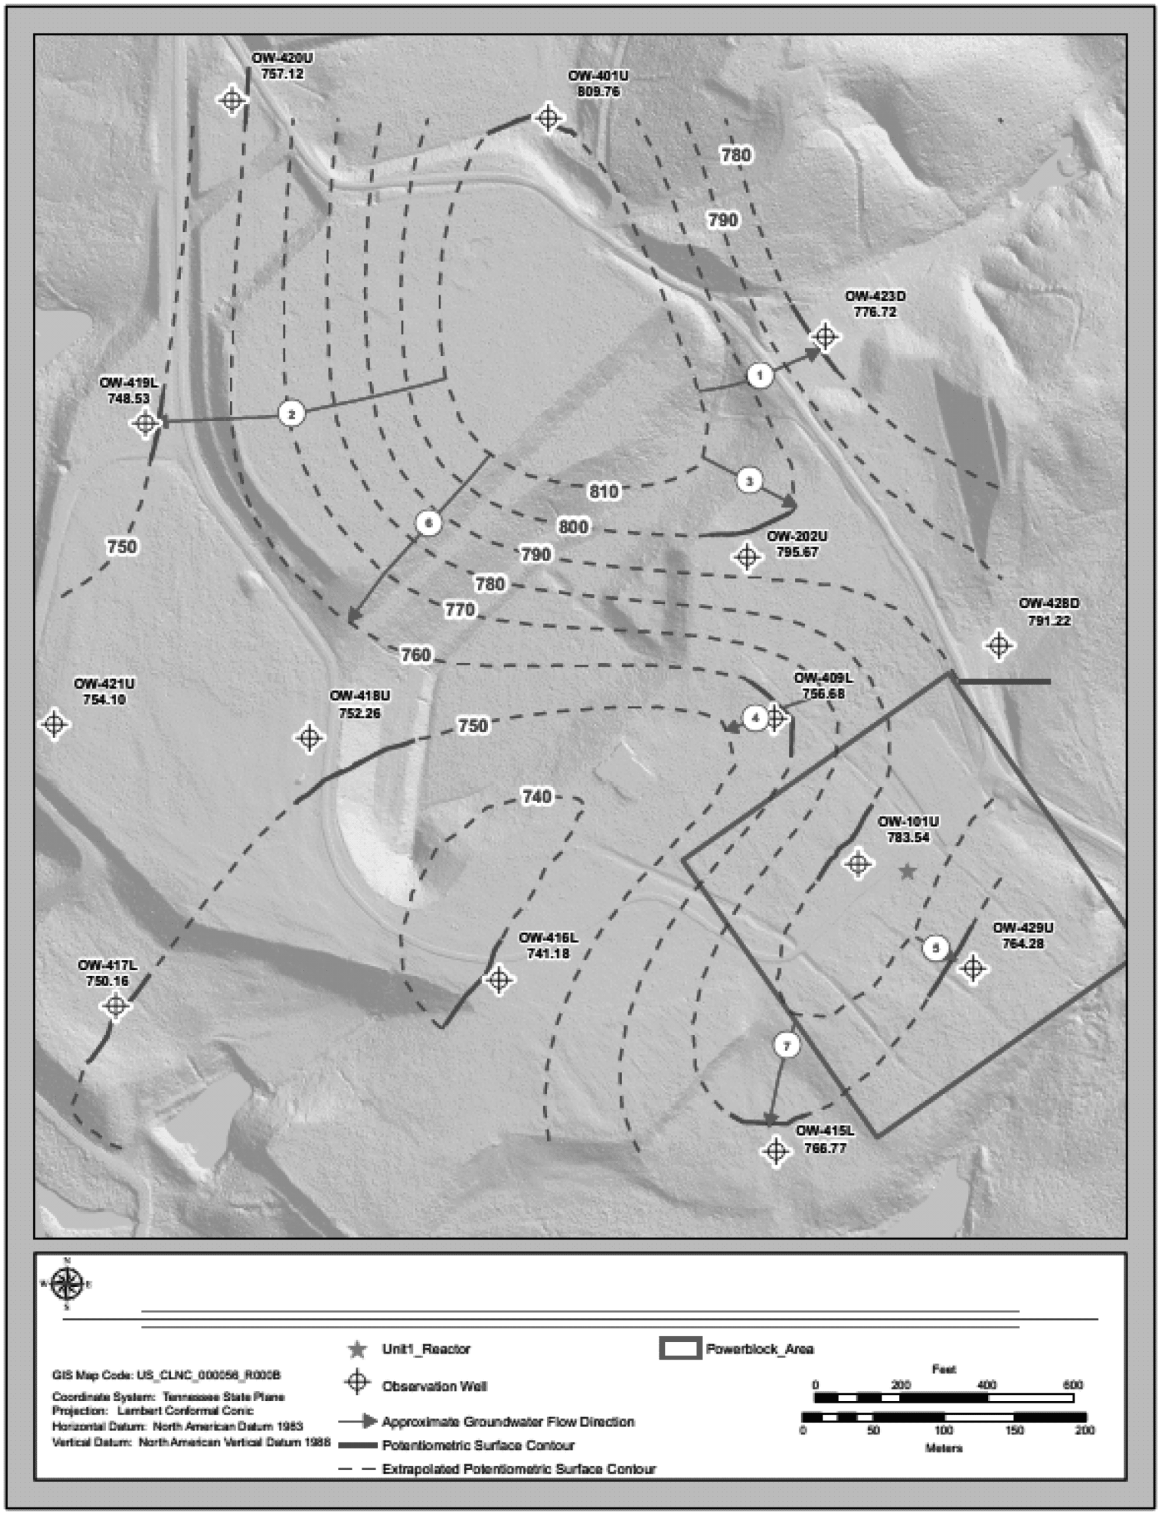

Figure 2.4.12-28R Potentiometric Surface Map for August 10, 2015

Replace Figure 2.4.12-40 with the following:

Figure 2.4.12-40R Plan View of the Profile Model with Grids

Replace Figure 2.4.12-41 with the following:

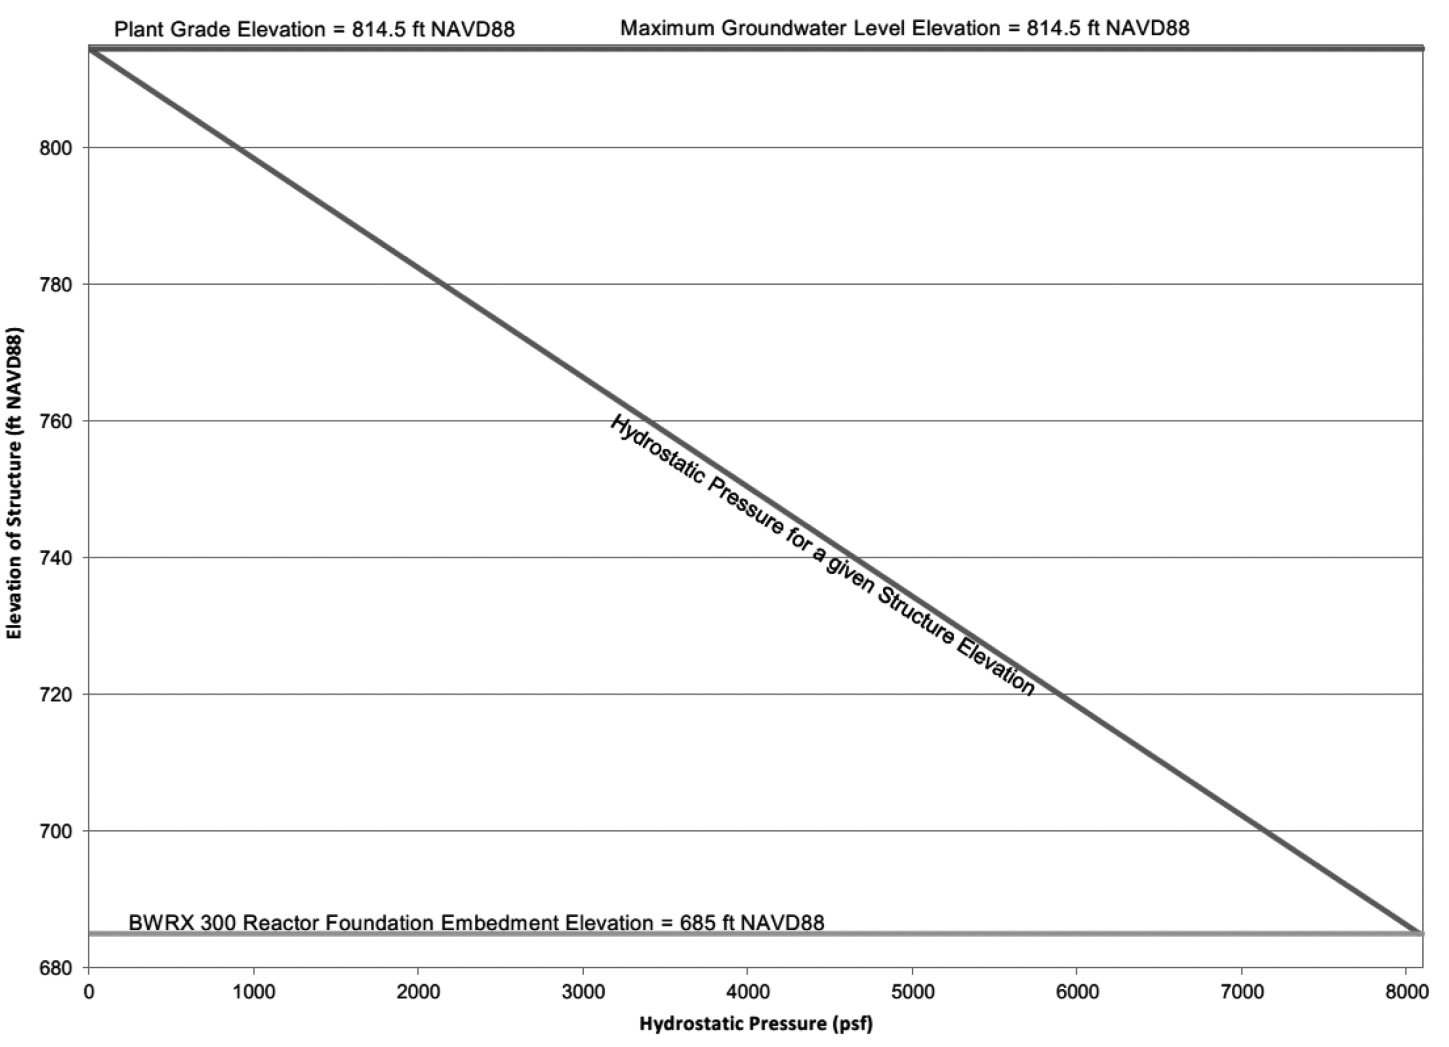

Figure 2.4.12-41R Maximum Hydrostatic Pressure

Appendix 2.4.12B Aquifer Pumping Test Results

2.4.12B Aquifer Pumping Test Results

2.4.12B.1.1 Purpose

Replace Figure 2.4.12B-1 with Figure 2.4.12B-1R in the first paragraph of ESPA SSAR Section 2.4.12B.1.1.

Replace Figure 2.4.12B-1 with the following:

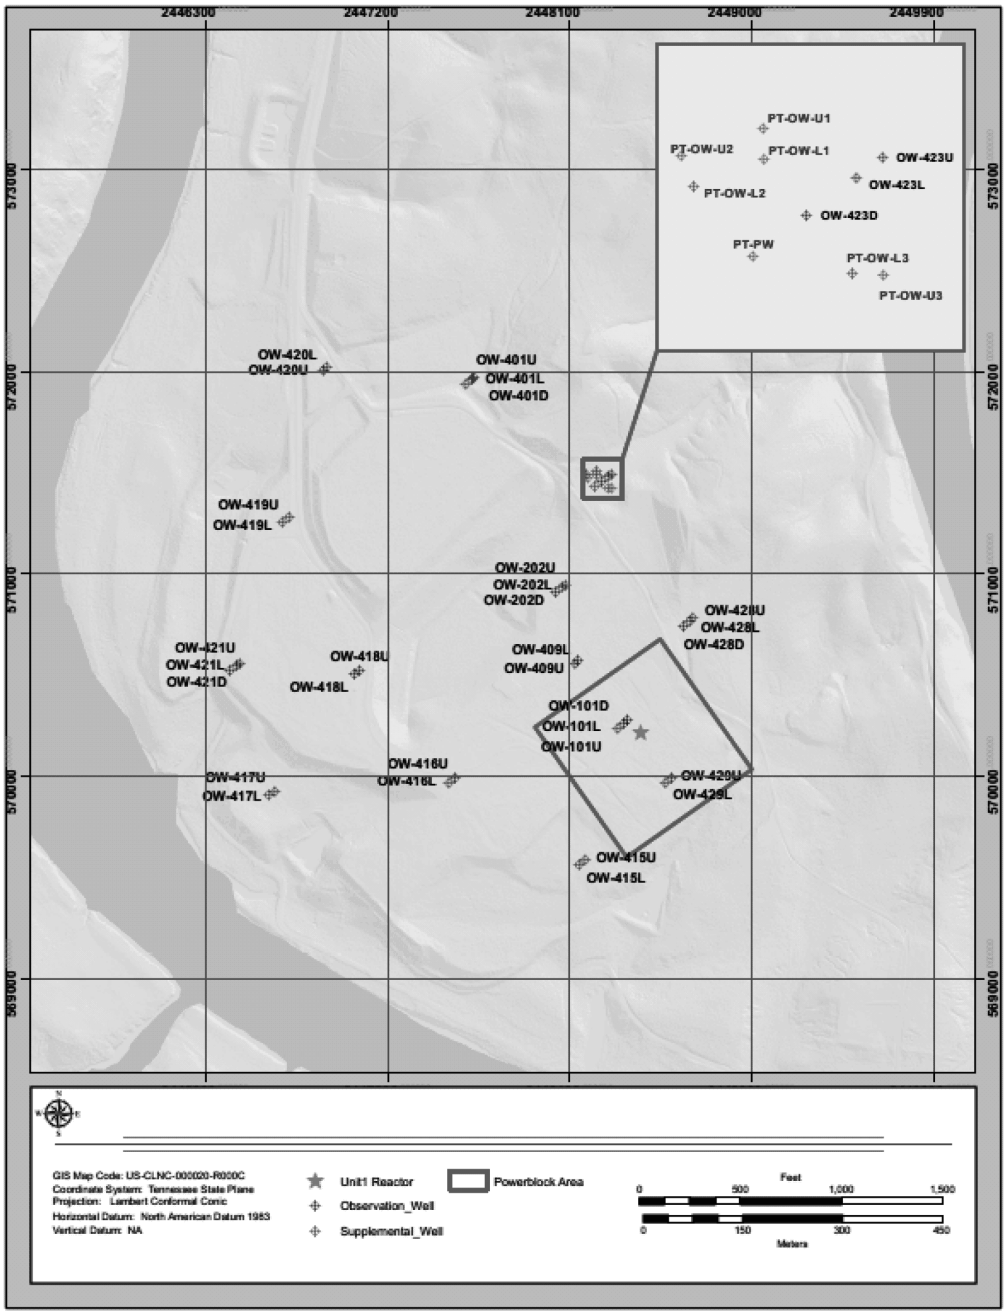

Figure 2.4.12B-1R Location of the Site Observation Wells

Appendix 2.4.12C Groundwater Flow Model for the Clinch River Nuclear Site

2.4.12C Groundwater Flow Model for the Clinch River Nuclear Site

2.4.12C.1 Objective and Scope

Replace the first paragraph of ESPA SSAR Section 2.4.12C.1 with the following:

The CRN Site groundwater flow model for the CRN Site in Roane County, Tennessee is prepared to evaluate groundwater levels during the operation of the BWRX-300 SMR constructed at the site. The primary objective of the groundwater model is to assess the post-construction maximum groundwater levels for BWRX-300 SMR power block area.

Replace the third bullet of the second paragraph of ESPA SSAR Section 2.4.12C.1 with the following:

- Developing a pre-construction site model to simulate maximum water level at and around the BWRX-300 SMR power block area and compare against the observed maximum water level

Replace the fifth bullet of the second paragraph of ESPA SSAR Section 2.4.12C.1 with the following:

- Performing predictive post-construction simulations to determine maximum groundwater levels at and around the BWRX-300 SMR power block area

2.4.12C.3 Site-Specific Information

Replace Figure 2.4.12-4 with Figure 2.4.12-4R in the fourth and sixth sentences of the third paragraph of ESPA SSAR Section 2.4.12C.3.

2.4.12C.3.1 Groundwater Level Measurements

Replace the first paragraph of ESPA SSAR Section 2.4.12C.3.1 with the following:

Groundwater level measurements were taken from 34 groundwater observation wells of which six locations consisted of three-well clusters, and eight locations consisted of two-well clusters. The locations of the wells are shown in Figure 2.4.12C-4R. The footprint of the BWRX-300 power block area is shown in Figure 2.4.12C-4R.

2.4.12C.3.2 Groundwater Level and Hydraulic Gradient Analysis

Replace Figure 2.4.12C-5 with Figure 2.4.12C-5R in the first bullet of the first paragraph of ESPA SSAR Section 2.4.12C.3.2.

Replace the third bullet of the first paragraph of ESPA SSAR Section 2.4.12C.3.2 with the following:

- The maximum water level elevation measured during the monitoring period (September 24, 2013 to March 16, 2014) in the general area of the BWRX-300 SMR power block area was 800.3 ft NAVD88 at observation well OW-202U.

2.4.12C.3.3 Packer Test Analysis

Replace Figure 2.4.12C-6 with Figure 2.4.12C-6R in the first sentence of the first paragraph of ESPA SSAR Section 2.4.12C.3.3.

2.4.12C.3.4 Slug Test Analysis

Replace Figure 2.4.12C-4 with Figure 2.4.12C-4R in the first sentence of the first paragraph of ESPA SSAR Section 2.4.12C.3.4.

2.4.12C.3.5 Aquifer Pumping Test Analysis

Replace the first paragraph of ESPA SSAR Section 2.4.12C.3.5 with the following:

An aquifer pumping test was conducted in the vicinity of OW-423 U/L/D well series and included seven supplemental wells (Figure 2.4.12C-4R). Transmissivity, storage coefficient, and hydraulic conductivity values were estimated from the drawdown and recovery plots of the pumping test observation wells using the Hantush-Jacob solution for a leaky aquifer with partial penetration and no aquitard storage.

2.4.12C.3.6 Hydrogeologic Data - Literature Information

Replace the first sentence of the fifth paragraph of ESPA SSAR Section 2.4.12C.3.6 with the following:

CRBRP on-site observation water level measurements indicated up to 25 ft fluctuation in water levels.

2.4.12C.3.7 Recharge Data – Literature Information

Replace the first sentence of the second bullet of the third paragraph of ESPA SSAR Section 2.4.12C.3.7 with the following:

- Bailey (Reference 2.4.12C-2) investigated the distribution of recharge in a cross-sectional, finite-difference model of the waste burial grounds at the ORR. Based on this model, most of the recharge occurs on the ridges of Pine Ridge (approximately two miles north of the BWRX-300 SMR power block area) and Chestnut Ridge (approximately one mile north of the BWRX-300 SMR power block area).

2.4.12C.4 Conceptual Site Model and Assumptions

Replace #5 in the fourth paragraph of ESPA SSAR Section 2.4.12C.4 with the following:

5. The fill, residual soil, and weathered bedrock units (regolith) along with the shallower depths of the competent bedrock units act as a porous medium (Figure 2.4.12C-12R (Sheet 1 of 11) and Figures 2.4.12C-12 (Sheets 2-11)). The shear zone depicted on Figures 2.4.12C-12 (Sheets 6 to 10) represents a laterally continuous interval of calcite-filled and cemented fractures in the lower Eidson. As these fractures are completely healed, they do not represent a zone of secondary porosity that would be conducive to preferential groundwater flow. Webster and Bradley (Reference 2.4.12C-37) state that groundwater flow in the regolith is characteristic of both porous media as well as fracture controlled flow at the nearby ORNL Site.

2.4.12C.5 Numerical Model

Replace the first two paragraphs of ESPA SSAR Section 2.4.12C.5 with the following:

Figure 2.4.12C-13R presents a site layout of Profile A and Profile C and the power block area of Unit 1 of the GE-Hitachi BWRX-300. Geotechnical borings (referred to as MPs) are concentrated within the power block area and centered near borings MP-101 and MP-202 (Figure 2.4.12C-13R). Based on geology observed in the geotechnical borings, most of the footprint of the power block area lies within the Chickamauga Group of rocks (interbedded siltstone and limestone), whereas the Knox Group (comprised mostly of dolomite) outcrops in the northern extremities of the power block area as indicated on Figure 2.4.12C-13R. Within the power block area, the Knox is significantly deeper. For example, at the MP-202 and MP-101 locations, it is encountered at a depth of approximately 450 and 1000 ft bgs, respectively, while at MP-423 and MP-426 the Knox is first encountered at a depth of approximately 30 to 50 ft bgs.

Two, two-dimensional, vertical profile, groundwater models were developed along the strike of the bedding planes (approximately N52°E) for the CRN Site. Figure 2.4.12C-13R shows the plan view of the profile models. Profile A intersects and lies close to the MP-202 series of geotechnical borings while Profile C (Profile B is not used) intersects the MP-101 series of geotechnical borings and Unit 1 of the BWRX-300 power block area (Figure 2.4.12C-13R). Both profiles fall along a three-cluster groundwater monitoring well series (OW-202 U/L/D and OW-101 U/L/D). The geologic formations present along the two profiles are different; Profile A mostly intersects the Fleanor Shale Member of the Lincolnshire Formation, while Profile C mostly intersects the Benbolt Formation. The hydraulic conductivity distribution along these lines, determined from the slug and packer tests, is also different (Table 2.4.12C-6). The combination of a concentration of geotechnical borings in two different clusters and the difference in hydraulic conductivity values led to the need to create two profile models to adequately represent the area.

Replace the eighth sentence of the third paragraph of ESPA SSAR Section 2.4.12C.5 with the following:

The profile models are used to provide conservative estimates of the maximum groundwater heads below SC1 structures.

Replace the last paragraph of ESPA SSAR Section 2.4.12C.5 with the following:

The groundwater model was developed using the pre- and post-processor groundwater modeling software, Groundwater Vistas, Version 8.19, Build 4. The numerical code used to simulate the profile models is MODFLOW-SURFACT, Version 3.0, as implemented in Groundwater Vistas (Reference 2.4.12C-11).

2.4.12C.5.2 Model Layers

Delete the last sentence of the first paragraph of ESPA SSAR Section 2.4.12C.5.2.

2.4.12C.6.2 Groundwater Budget

Replace the seventh sentence of the first paragraph of ESPA SSAR Section 2.4.12C.6.2 with the following:

During the CRN Site subsurface field investigation, seepage was observed in some outcrops in the low lying CRBRP disturbed area.

2.4.12C.7 Post-Construction Modeling

Replace ESPA SSAR Section 2.4.12C.7 with the following:

Post-construction modeling is performed to estimate the response of groundwater levels to the inclusion of the following BWRX-300 specific structures in the model: radwaste building, reactor building, and turbine building. A single BWRX-300 SMR developed by General Electric (GE) Hitachi is planned for the CRN Site and included as Unit 1 in a Construction Permit Application (Figure 2.4.12C-23R (Sheet 1 of 2)). The excavation depth of the reactor building is 129.5 feet below grade (Figure 2.4.12C-23R (Sheet 2 of 2)). There will be some backfill with lean concrete between the excavation depth and the bottom of the basemat. Post-construction model was only done for Profile C because it coincides with the location of the power block structures (Figure 2.4.12C-24R and 2.4.12C-25R) and thus post-construction simulations for Profile A were not performed because the Construction Permit Application is being submitted for only one unit.

2.4.12C.7.1 Modifications to Pre-Construction Models

Replace ESPA SSAR Section 2.4.12C.7.1 with the following:

The structure of the model along with hydraulic conductivity distributions for subsurface layers remained the same as the pre-construction model; however, some nominal changes were made to the Profile C model to include the representative structures and placement of construction fill to raise the site grade (Figure 2.4.12C-26R). The following describes the changes between the pre- and post-construction models:

- The site grade elevation within the power block, which includes the radwaste, reactor, control and turbine buildings, was set to an elevation of 814.5 ft NAVD88 (Figures 2.4.12C-23R (Sheet 1 of 2), Figure 2.4.12C-23R (Sheet 2 of 2) and 2.4.12C-24R). The site grade outside of the power block was adjusted to reflect the elevations shown in Figure 2.4.12C-23R (Sheet 1 of 2).
- Construction fill was included in areas where the existing site grade was raised to the design site grade. The hydraulic conductivity was calculated using the empirical formula of Reference 2.4.12C-8, which requires the D_{10} and D_{60} grain size values. These grain-size values were obtained from the Tennessee Department of Transportation (TDOT) specification for Type A, Grading D aggregate. Table 2.4.12C-27R shows the grain-size distribution (lower bound, upper bound, average) for TDOT Type A, Grading D aggregate. Table 2.4.12C-11R provides the calculated hydraulic conductivity values based on the upper, lower, and average D_{10} and D_{60} for the specified grain-size distributions. The “C2” values for D_{10} and D_{60} shown in Figure 2.4.12C-27R resulted in the lowest calculated hydraulic conductivity value of 1.5 ft/day (5.3x10-4 cm/s). To conservatively estimate maximum groundwater heads in the power block area, a construction fill hydraulic conductivity of 1.5 ft/day was assigned in the post-construction model.
- The site grade in the power block area corresponds to an elevation of 814.5 ft NAVD88. Impermeable structures embedded below the water table (e.g., reactor building) are represented as inactive (no flow) cells in the Profile C model (Table 2.4.12C-26R). Those buildings with shallow embedment depths do not have any appreciable impact on groundwater flow and are not represented.
- A model layer was added below the bottom of the reactor building (layer 8) to allow the model to calculate the maximum head imposed at the base of the foundation. The hydraulic conductivity for this layer was assigned the same value as the pre-construction model layer 7. Figure 2.4.12C-26R show hydraulic conductivity distributions for the layers in the post-construction model cross-section for Profile C.
- The width of the power block area in the cross-sectional model approximates the width of the power block in the site layout drawing (Figure 2.4.12C-24R).
- The bottom of the reactor building was set to an elevation of 685 ft NAVD88, which is 129.5 ft below the grade elevation of 814.5 ft NAVD88.
- The bottom of the turbine building foundation was set to an elevation of 800 ft NAVD88, which is 14.5 ft below the grade elevation of 814.5 ft NAVD88. Existing fill, soil, and weathered rock beneath the turbine building is replaced by construction fill. Although the Profile C model

does not exactly pass through the turbine building (as shown in Figure 2.4.12C-25R), nevertheless the turbine building was conservatively represented in the Profile C post-construction model.

2.4.12C.7.2 Results

Replace ESPA SSAR Section 2.4.12C.7.2 with the following:

The objective of the groundwater modeling as outlined in Subsection 2.4.12C.1 is to determine post-construction maximum groundwater head in the power block area.

The maximum piezometric head underneath the Unit 1, BWRX-300 reactor building is 814.5 ft NAVD88, which is the same as the power block plant site grade elevation (Table 2.4.12C-12R and Figures 2.4.12C-28R and 2.4.12C-29R). Figure 2.4.12C-29R depicts groundwater flow away from the power block.

The GEH Licensing Topical Report, BWRX-300 Advanced Civil Construction and Design Approach, provides a generic conservative groundwater level located at plant grade (Reference 2.4.12C-39). This groundwater level is used in stability calculations to account for the buoyancy force.

The maximum piezometric head underneath the turbine building foundation is 814.2 ft NAVD88, which is 0.3 ft below the plant site grade elevation (Table 2.4.12C-12R and Figures 2.4.12C-28R and 2.4.12C-29R).

Sensitivity analysis was conducted by varying the construction fill hydraulic conductivity to 50.7 ft/day (as shown in Table 2.4.12C-11R for curve C1) but the piezometric head underneath the Unit 1, BWRX-300 reactor building remains unchanged, i.e., to the site grade of 814.5 ft NAVD88. Piezometric head underneath the turbine building was 811.5 ft NAVD88, i.e., decreased by 2.7 ft from the simulated head of 814.2 ft NAVD88 with a construction fill hydraulic conductivity of 1.5 ft/day.

2.4.12C.8 Conclusions

Replace ESPA SSAR Section 2.4.12C.8 with the following:

The following are concluded from the groundwater modeling results:

- Pre-construction groundwater model simulated heads closely matched the observed maximum groundwater heads at observation wells near the proposed location of the BWRX-300 SMR for this modeling exercise.
- Groundwater heads are sensitive to recharge in the groundwater model, similar to observed water level response due to precipitation during the subsurface investigations at the CRN Site. Higher recharge translates to higher water levels. A uniform recharge of 8.76 in./yr in the pre-construction model results in water levels close to the land surface at the power block area. This provides a conservative estimate with respect to the maximum water levels under predictive model simulations.

- Simulated piezometric head underneath the Unit 1 BWRX-300 reactor building foundation embedment is 814.5 ft NAVD88, which is at the plant grade. The piezometric head underneath the turbine building embedment foundation is 814.2 ft NAVD88.
- The calculated piezometric head under post-construction simulation underneath the Unit 1 BWRX-300 reactor building foundation reaches the plant grade elevation of 814.5 ft NAVD88 and meets the BWRX-300 generic groundwater heads as described in the GEH Licensing Topical Report, BWRX-300 Advanced Civil Construction and Design Approach.

2.4.12C.9 References

Add the following Reference to ESPA SSAR Section 2.4.12C.9:

Delete ESPA SSAR Figures 2.4.12C-30 through 2.4.12C-32.

2.4.13 Accidental Releases of Liquid Effluents to Ground and Surface Waters

Replace the first paragraph of ESPA SSAR Section 2.4.13 with the following:

The purpose of this section is to provide a conservative analysis of a postulated, accidental release of radioactive liquid effluents to the environment at the CRN Site (Figure 2.4.13-1R), in accordance with the guidance provided in Branch Technical Position (BTP) 11-6, Postulated Radioactive Releases Due to Liquid-Containing Tank Failures. The accident scenario is presented. The conceptual model used to evaluate radionuclide transport is discussed, along with potential exposure pathways for water users. The radionuclide transport model is described, and exposure concentrations are calculated. The radionuclide concentrations to which a water user might be exposed, and the associated dose are compared against regulatory limits.

Rename and Replace ESPA SSAR Section 2.4.13.1 with the following:

2.4.13.1 Postulated Accidental Scenario

It is postulated that a Liquid Waste Management System (LWMS) tank outside of containment ruptures with its contents released to the environment. The BWRX-300 LWMS tank having the volume and inventory that would result in the maximum dose to the public was determined to be the Refueling Water Storage Tank (RWST), which contains unprocessed reactor coolant and has a capacity of 165,000 gallons and total activity of 2.43E+03 Curie (Ci). Table 2.4.13-1R lists the radionuclides and activities expected to be present in the RWST. It is assumed that 80 percent of the tank volume is transferred instantaneously to the groundwater at a point within the power block area and no credit is taken for the time that the radionuclides may take (and the associated radioactive decay and other attenuation mechanisms acting during unsaturated zone transport) to travel from the RWST to the saturated zone. Analyzing a release of 80 percent of the tank volume is based on BTP 11-6, which states the following: “The radionuclide inventory for the tank and its components assumed to fail should be based on a conservative estimate of 80 percent capacity of that tank and its components.”

BTP 11-6 indicates that an applicant may take credit for mitigating design features provided they demonstrate that “such features are durable and passive, and that the receiving system has the storage capacity to hold the expected volume of liquid wastes.” In cases where the mitigating design features of tanks can be demonstrated, a consequence analysis in the context of SRP 11.2 and BTP 11-6 may not be required. However, BTP 11-6 further states “the presence of mitigating design features does not change the guidance in SRP 2.4.12 that relates to demonstrating the adequacy of the site’s hydrogeologic properties via a conservative analysis that uses combined literature data and site-specific parameters characterizing transport mechanisms, such as aquifer materials, hydraulic conductivity, and porosity, etc.” Therefore, the analysis presented in this section is required, independent of any acceptable mitigating design features.

Rename and Replace ESPA SSAR Section 2.4.13.2 with the following

2.4.13.2 Exposure Scenarios

BTP 11-6 requires the evaluation of the following exposure scenarios:

A. Direct water use - This scenario assumes that members of the public would consume drinking water withdrawn, near or at the point of entry in an unrestricted area. The sources of water include a groundwater well, or from a surface water body or river.

B. Indirect water use - This scenario assumes the use of water in indirect human consumption. Such scenarios may include livestock watering or irrigation of grazing pastures, consumption of animal products (meat and milk products), fish and invertebrate consumption, crop irrigation and consumption of such crops, or water used as an ingredient in food products or in food processing.

C. Combined use of water - This scenario assumes both direct and indirect water use. In such an instance, the scenarios would be modeled separately, and the resulting doses would be summed and compared to the acceptance criteria.

For the consequence analysis, BTP 11-6 defines the point of entry in unrestricted areas as a location beyond the site boundary where the applicant has no administrative controls that could be used to restrict the use of surface water or groundwater resources. When considering surface water resources, the selected point of entry in unrestricted areas should be identified as that location in a surface water body or stream affected only by near-field dilution near the point of entry. BTP 11-6 defines “a member of the public” to be any individual who is not receiving an occupational dose. For the CRN Site, the point of entry in an unrestricted area is assumed to be the right bank (looking downstream) of the Clinch River arm of the Watts Bar Reservoir (hereafter referred to as the Reservoir) at which point the surface water could be used by a member of the public.

Downstream of the CRN Site, the nearest surface water intake is for the former Oak Ridge Bear Creek Road Plant, which used the Clinch River as a source of industrial water and is located downstream of the CRN Site as shown on Table 2.4.1-1 and Figure 2.4.1-1 (Location No. 45). The Oak Ridge Bear Creek Road Plant was also known as the West End Water Treatment Plant (WTP) when the City of Oak Ridge assumed control of the facility. The plant ceased water production on September 30, 2014. Subsequently, this plant has been completely decommissioned and there are no plans to use this facility in the future because the City of Oak Ridge is constructing a new water treatment facility upstream of the CRN Site.

Add Section 2.4.13.3:

2.4.13.3 Dose Acceptance Criteria

Dose acceptance criteria are based on doses to a member of the public. BTP 11-6 provides the following dose acceptance criteria:

1. Radioactive releases associated with the postulated failure of a tank and components should not do the following:

    a. Result in radioactive material concentrations leading to a dose in excess of 100 millirem (mrem) at the point of entry into the nearest existing or a known future water supply when (1) used as a source of water for direct human consumption or (2) used indirectly through livestock watering or irrigation of grazing pastures, consumption of animal products (meat and milk products), fish and invertebrate consumption, crop irrigation and consumption of such crops, or used as an ingredient in food products or food processing, or

    b. Result in a total dose in excess of 100 mrem in instances where a scenario assumes the dual use of water, direct and indirect usage. In such an instance, the dose from each scenario must be derived separately and the resulting doses must be added, with the summation of doses compared to the dose acceptance criteria.

2. Complying with the dose acceptance criteria does not relieve the applicant from complying with the Table 2, Column 2 effluent concentration limits (ECLs) and the unity rule of Appendix B to 10 CFR Part 20.

Based on the above, dose acceptance and regulatory compliance requires satisfactory demonstration of the following: (1) compliance with the dose standards described above, and (2) compliance with the ECLs and unity rule of 10 CFR 20, Appendix B.

Renumber ESPA SSAR Section 2.4.13.3 to Section 2.4.13.4.

2.4.13.4 Primary Conceptual Model

Renumber Figure 2.4.13-2 in the first sentence of the first paragraph to Figure 2.4.13-2R.

Replace the second paragraph of ESPA SSAR Section 2.4.13.4 with the following:

Following release, it is assumed that radionuclides travel through the construction fill material and the shallow, pervasively fractured bedrock before reaching the Reservoir (Figure 2.4.13-2R). The shortest distance between the BWRX-300 power block area and right bank of the Reservoir is approximately 1200 ft (Figure 2.4.13-1R). While the actual distance between the RWST and the Clinch River is longer, the 1200-ft distance provides a conservative estimate, as less travel time allows for less decay of radionuclides.

Replace the reference to Subsection 2.4.13.5 in the third paragraph with Subsection 2.4.13.6.

Renumber ESPA SSAR Section 2.4.13.4 to Section 2.4.13.5.

2.4.13.5 Alternate Conceptual Model

Renumber Figure 2.4.13-3 in the first paragraph to Figure 2.4.13-3R.

Renumber ESPA SSAR Section 2.4.13.5 to Section 2.4.13.6.

2.4.13.6 Radionuclide Transport Analysis

Replace the first paragraph of ESPA SSAR Section 2.4.13.6 with the following:

A radionuclide transport analysis has been conducted to estimate the radionuclide concentrations that might result in exposure to existing and future water users based on an instantaneous release of the radioactive liquid from the BWRX-300 RWST. Analysis of liquid effluent release commences with a screening model, using demonstratively conservative assumptions and coefficients. Radionuclide concentrations resulting from the screening analysis are then compared to the ECLs identified in 10 CFR 20, Appendix B, Table 2, Column 2, to determine acceptability. Further analysis, using more realistic modeling techniques, is conducted for the radionuclides identified in the screening analysis.

Renumber ESPA SSAR Section 2.4.13.5.1 to Section 2.4.13.6.1.

2.4.13.6.1 Radionuclide Transport in Groundwater and Surface Water

Replace the first paragraph of ESPA SSAR Section 2.4.13.6.1 with the following:

The effects of transport in groundwater and dilution in the Reservoir are modeled using an analytical approach outlined in Reference 2.4.13-1 for quantifying solute flux through groundwater following an instantaneous release and the resulting dilution in the intercepting surface water body. The flux in this case is given by Equation 4.41 of Reference 2.4.13-1. Multiplying this equation by V_T/Q gives the following expression for the dilution factor:

Renumber Reference 2.4.13-21 in the second sentence of the last paragraph to Reference 2.4.13-2.

Renumber ESPA SSAR Section 2.4.13.5.2 to Section 2.4.13.6.2 and Revise the title to Estimation of Source Concentrations (C_0).

2.4.13.6.2 Estimation of Source Concentrations (C_0)

Replace ESPA SSAR Section 2.4.13.6.2 with the following:

Application of dilution factors obtained from Equation 2.4.13-1 requires a source concentration (C_0) for each radionuclide of concern. This is obtained by dividing the radionuclide activity in the

RWST by the tank volume. However, some radionuclides produce daughter products that are important dosimetrically but are not accounted for in the RWST inventory listed in Table 2.4.13-1R. Peak activity was determined by simulating decay of the source term inventory at various time steps ranging from 0 to 50 years for relevant radionuclides to capture the maximum activity of daughter products (Table 2.4.13-1R). The maximum activity for each radionuclide was selected and divided by the release volume to arrive at C_0 values for these radionuclides (Table 2.4-13-2R).

This approach effectively assumes that the contents of an RWST are allowed to sit idle for 50 years after the plant has ceased operating and then accidentally released to the groundwater; however, it is more likely that the RWST will be emptied when the plant shuts down. The approach overestimates the total activity released, as parent radionuclide activities are not decreased while daughter product activities are increased. Although Nb-93m did not reach peak activity within 50 years, it is likely that the RWST contents will be emptied within this period. In addition, the parent radionuclide, Zr-93, is very long lived (half-life over 1 million years) and, therefore, significant concentrations of Nb-93m, which is relatively short-lived with a half-life of about 16 years, will not accumulate.

Renumber ESPA SSAR Section 2.4.13.5.3 to Section 2.4.13.6.3.

2.4.13.6.3 Input Parameters

Renumber ESPA SSAR Section 2.4.13.5.3.1 to Section 2.4.13.6.3.1.

2.4.13.6.3.1 Tank Volume and Volume Released (VT)

Replace the first paragraph of ESPA SSAR Section 2.4.13.6.3.1 with the following:

The RWST volume is 165,000 gallons as described in Subsection 2.4.13.1. It is assumed that 80 percent of the tank volume is transferred instantaneously to the groundwater at a point within the power block area. Thus, 132,000 gallons (17,647 cubic feet) is used as input for V_T in Equation 2.4.13-1.

Renumber ESPA SSAR Section 2.4.13.5.3.2 to Section 2.4.13.6.3.2.

2.4.13.6.3.2 Groundwater Pore Velocity (U) and Groundwater Travel Time

Replace ESPA SSAR Section 2.4.13.6.3.2 with the following:

The magnitude of groundwater pore velocity, U, is computed using the relation (Equation 4.8 of Reference 2.4.13-1):

$$U = \frac{K}{n_e}\frac{dh}{dx} \qquad \text{Equation 2.4.13-2}$$

---

where:

K = hydraulic conductivity (L/T)

n_e = effective porosity (unitless)

$\frac{dh}{dx}$ = hydraulic gradient (L/L)

A hydraulic conductivity of 2.6 feet per day (ft/d) is used based on the results of the onsite aquifer pumping test analysis as discussed in Subsection 2.4.12.2.4.1. This is the computed hydraulic conductivity for the observation well oriented along the predominant groundwater flow path (parallel to strike).

The effective porosity was assigned a value of 0.0467 based on testing performed at the Oak Ridge Reservation (References 2.4.13-3 and 2.4.13-4) as discussed in Subsection 2.4.12.2.4.1. The selected value is the average of 90 tests conducted using immersion-saturation porosimetry.

Based on site water level measurements, as discussed in Subsection 2.4.12.2.2, the horizontal hydraulic gradient at the CRN Site ranges from 0.02 to 0.12. The mean, 0.07, is used as the representative horizontal hydraulic gradient.

The resulting groundwater pore velocity (U), computed using Equation 2.4.13-2, is about 3.9 ft/d. The distance from the power block area to the Reservoir is approximately 1200 ft. Thus, the groundwater travel time from the edge of the power block area to the Reservoir is estimated to be about 308 days (1200 ft / 3.9 ft/d).

Renumber ESPA SSAR Section 2.4.13.5.3.3 to Section 2.4.13.6.3.3.

2.4.13.6.3.3 River Flow Rate (Q)

Renumber Reference 2.4.13-3 in the third sentence of the third paragraph to Reference 2.4.13-1.

Renumber ESPA SSAR Section 2.4.13.5.3.4 to Section 2.4.13.6.3.4.

2.4.13.6.3.4 Aquifer Bulk Density (ρb)

Renumber Reference 2.4.13-6 in the second sentence of the first paragraph to Reference 2.4.13-5.

Renumber ESPA SSAR Section 2.4.13.5.3.5 to Section 2.4.13.6.3.5.

2.4.13.6.3.5 Aquifer Longitudinal Dispersivity (α_L)

Renumber Reference 2.4.13-7 in the first paragraph to Reference 2.4.13-6.

Replace the second paragraph of ESPA SSAR Section 2.4.13.6.3.5 with the following:

The length scale, x, in the above equation is in meters and α_L is also in meters. The length scale used in the above equation is 365.8 meters (m) (1200 ft) for the transport distance from the edge of power block area to the edge of the Reservoir. The estimated α_L is 8.05 m (26.4 ft).

Renumber ESPA SSAR Section 2.4.13.5.3.6 to Section 2.4.13.6.3.6.

2.4.13.6.3.6 Radioactive Half-Life and Decay Constant

Replace ESPA SSAR Section 2.4.13.6.3.6 with the following:

Radioactive half-lives for the radionuclides under consideration were obtained from Reference 2.4.13-7. Radionuclide half-lives were used to calculate the decay constant for each radionuclide, which are given in Table 2.4-13-2R.

Renumber ESPA SSAR Section 2.4.13.5.3.7 to Section 2.4.13.6.3.7.

2.4.13.6.3.7 Distribution Coefficients (Kd)

Replace ESPA SSAR Section 2.4.13.6.3.7 with the following:

Distribution coefficients, K_d, were applied to selected radionuclides based on laboratory testing carried out using samples from the CRN Site as shown on Table 2.4.13-4. K_d is used in the computation of the retardation coefficient, R_d, using the relation:

$$R_d = 1 + \frac{\rho_b K_d}{n_e} \qquad \text{Equation 2.4.13-4}$$

where ρ_b is the bulk density and n_e is the effective porosity of the aquifer.

Non-zero K_d values were used for elements for which site-specific laboratory measurements were available. The geometric mean of the laboratory-derived K_d values was assigned as the representative value for each element. K_d test result summary statistics and analysis notes are presented in Table 2.4.13-4.

Renumber ESPA SSAR Section 2.4.13.6 to Section 2.4.13.7.

2.4.13.7 Radionuclide Concentration in the Reservoir

Replace the first two paragraphs of ESPA SSAR Section 2.4.13.7 with the following:

Minimum dilution factors and associated maximum concentrations in the Reservoir are provided in Table 2.4.13-5R. For screening purposes, dilution factors were initially calculated without considering the effects of sorption (using Equation 2.4.13-1 with $R_d = 1$). The resulting

---

concentrations in the Reservoir were compared against the ECLs. It was found that none of the radionuclides exceeded their respective ECLs. Summing of the C/ECL ratios gives a value of 4.34E-02, which is less than one and compliant with the unity rule of 10 CFR Part 20, Appendix B.

Further analysis accounting for sorption of the radioisotopes listed in Subsection 2.4.13.6.3.7 (Table 2.4.13-4) was performed. This resulted in further reductions in the estimated concentrations in the Reservoir for isotopes with non-zero K_d values (Table 2.4.13-5R). When accounting for sorption and retardation for those radionuclides where site-specific K_d values were determined, summing the C/ECL ratios yields a smaller value of 2.53E-04, demonstrating compliance with the unity rule by a large margin. These concentrations were carried forward for dose evaluation, as described in the Subsection 2.4.13.8.

Renumber Table 2.4.13-5 in the third paragraph to Table 2.4.13-5R.

Replace sixth paragraph of ESPA SSAR Section 2.4.13.7 with the following:

The distribution coefficient for radionuclides, for which no site-specific distribution coefficients are available (e.g., Y-91, Nb-95), is assumed to be zero, even though non-zero values are reported in literature. A larger retardation factor (associated with non-zero distribution coefficients) would result in longer radionuclide travel time, more radioactive decay, and lower concentrations in the Reservoir. In the case of Y, its chemistry is similar to a lanthanide and is often associated in the environment with lanthanides such as cerium (Ce) (Reference 2.4.13-8). The site-specific geometric mean K_d value for Ce is 54 milliliters per gram (mL/g) and thus the likely K_d value for Y is also 54 mL/g; however, the K_d value for Y has been conservatively assigned a value of zero. In addition, Reference 2.4.13-9 reports distribution coefficient values for Nb ranging from 80 to 100 mL/g, based on batch and column experiments conducted with crushed rock, whereas its K_d value has been conservatively assigned a value of zero. If the preceding K_d values were used for Y-91 and Nb-95 in the analysis, the calculated exposure concentrations for these radionuclides in the Reservoir would be essentially zero, and the dose to the receptor would be reduced.

Renumber ESPA SSAR Section 2.4.13.7 to Section 2.4.13.8.

2.4.13.8 Dose Evaluation

Renumber Table 2.4.13-5 in the first sentence of the first paragraph to Table 2.4.13-5R.

Renumber Reference 2.4.13-12 in the third sentence of the first paragraph to Reference 2.4.13-10.

Replace the third paragraph to the end of ESPA SSAR Section 2.4.13.8 with the following (Addresses COL Action Item 2.4-4):

The major inputs and assumptions are as follows:

- No dilution is credited beyond the concentrations shown in Table 2.4.13-5R

- Transit time to dose receptors is assumed to be zero
- Irrigation rate is assumed to be 1 inch per week, which bounds the actual rate near the plant of 0.24 inches per week (Reference 2.4.13-11)
- Consumption and usage rates are the default values for the maximally exposed individual from RG 1.109, Table E-5, while assuming that the time spent on boating and swimming is each the same as that for shoreline activities
- Exposure duration is assumed to be 1 year
- TEDE dose conversion factors for ingestion are obtained from Federal Guidance Report 11 (Reference 2.4.13-12)
- TEDE dose conversion factors for ground deposition and immersion are obtained from Federal Guidance Report 12 (Reference 2.4.13-13)

LADTAP II requires the source nuclide activities to be input in the units of Curies per year (Ci/y). The concentrations in Table 2.4.13-5R are converted into release rates (Ci/y) by multiplying by an arbitrary flow rate of 1 cfs, which is then entered as the liquid effluent discharge rate. LADTAP II divides the isotopic activity by the discharge rate to obtain the initial concentrations, causing the flow rate to cancel out. With the transit time to the dose receptor input as zero, LADTAP II calculates concentrations at the receptor that are identical to those in Table 2.4.13-5R. The resulting total dose from all exposure pathways is 0.62 mrem TEDE to an adult, the age group receiving the maximum dose. This dose is within the 10 CFR 20.1301 limit of 100 mrem TEDE.

Renumber ESPA SSAR Section 2.4.13.8 to Section 2.4.13.9.

NA = Not available (no published ECL)

* Indicates dilution factor approaching infinity and reservoir concentration approaching zero

C/ECL values less than 1.0E-06 are reported as zero

Figure 2.4.13-1R Minimum Distance from the BWRX-300 Power Block Area to the Clinch River Arm of the Watts Bar Reservoir

Replace Figure 2.4.13-2 with the following:

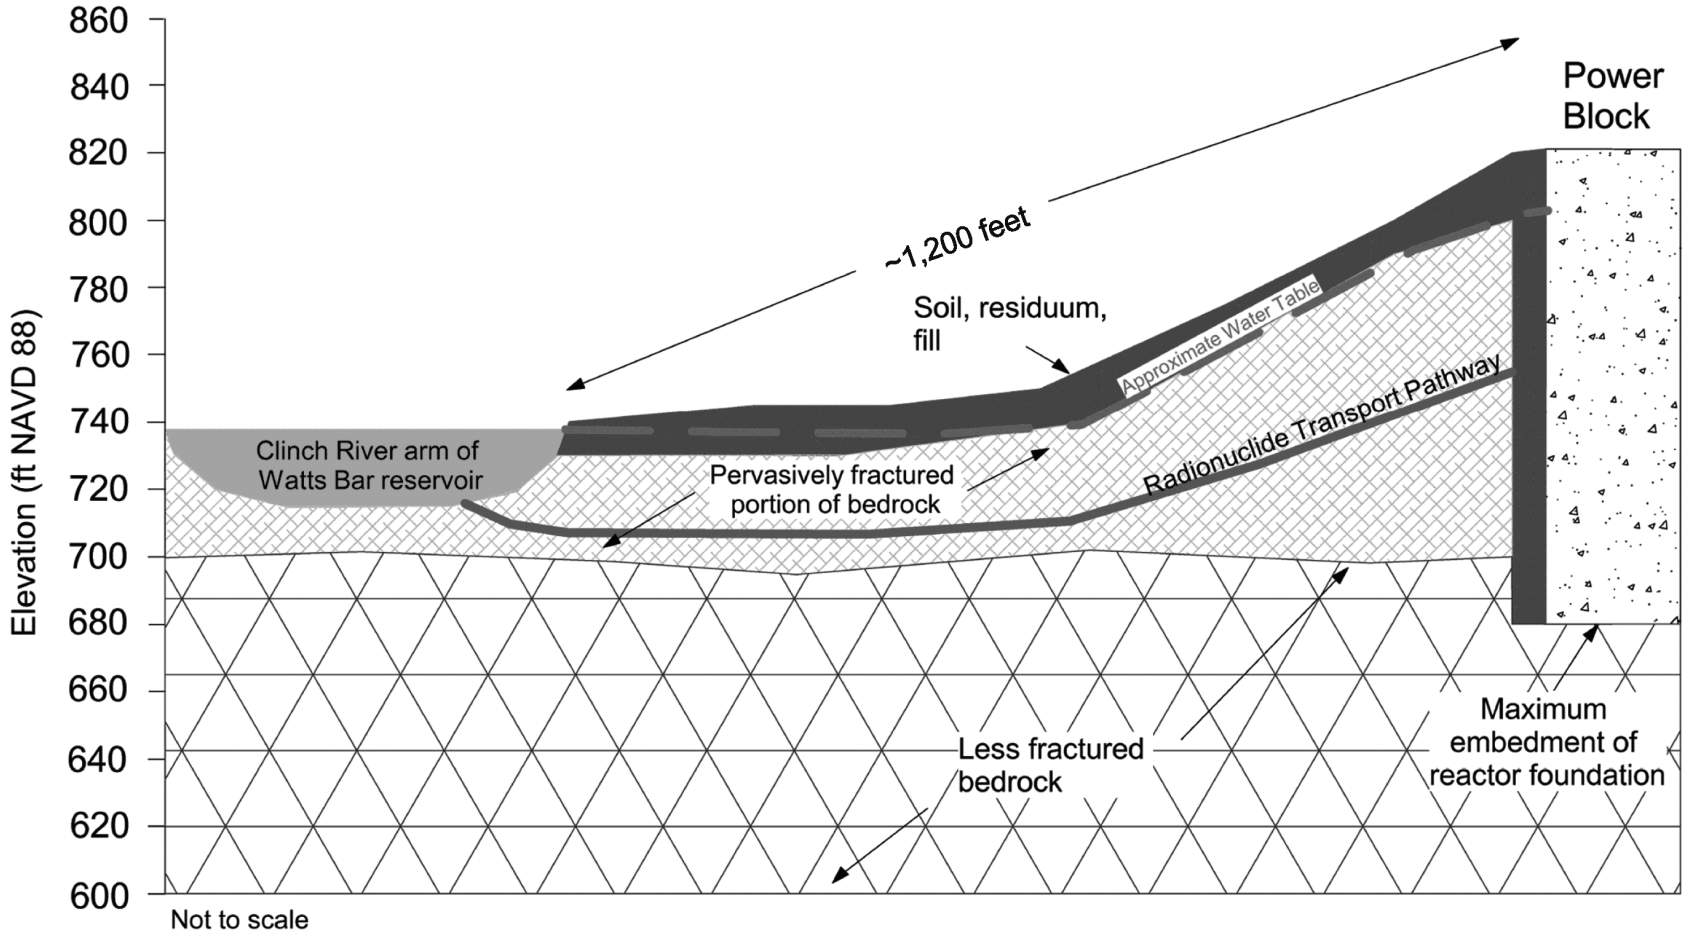

Figure 2.4.13-2R Conceptual Model for Radionuclide Transport

Replace Figure 2.4.13-3 with the following:

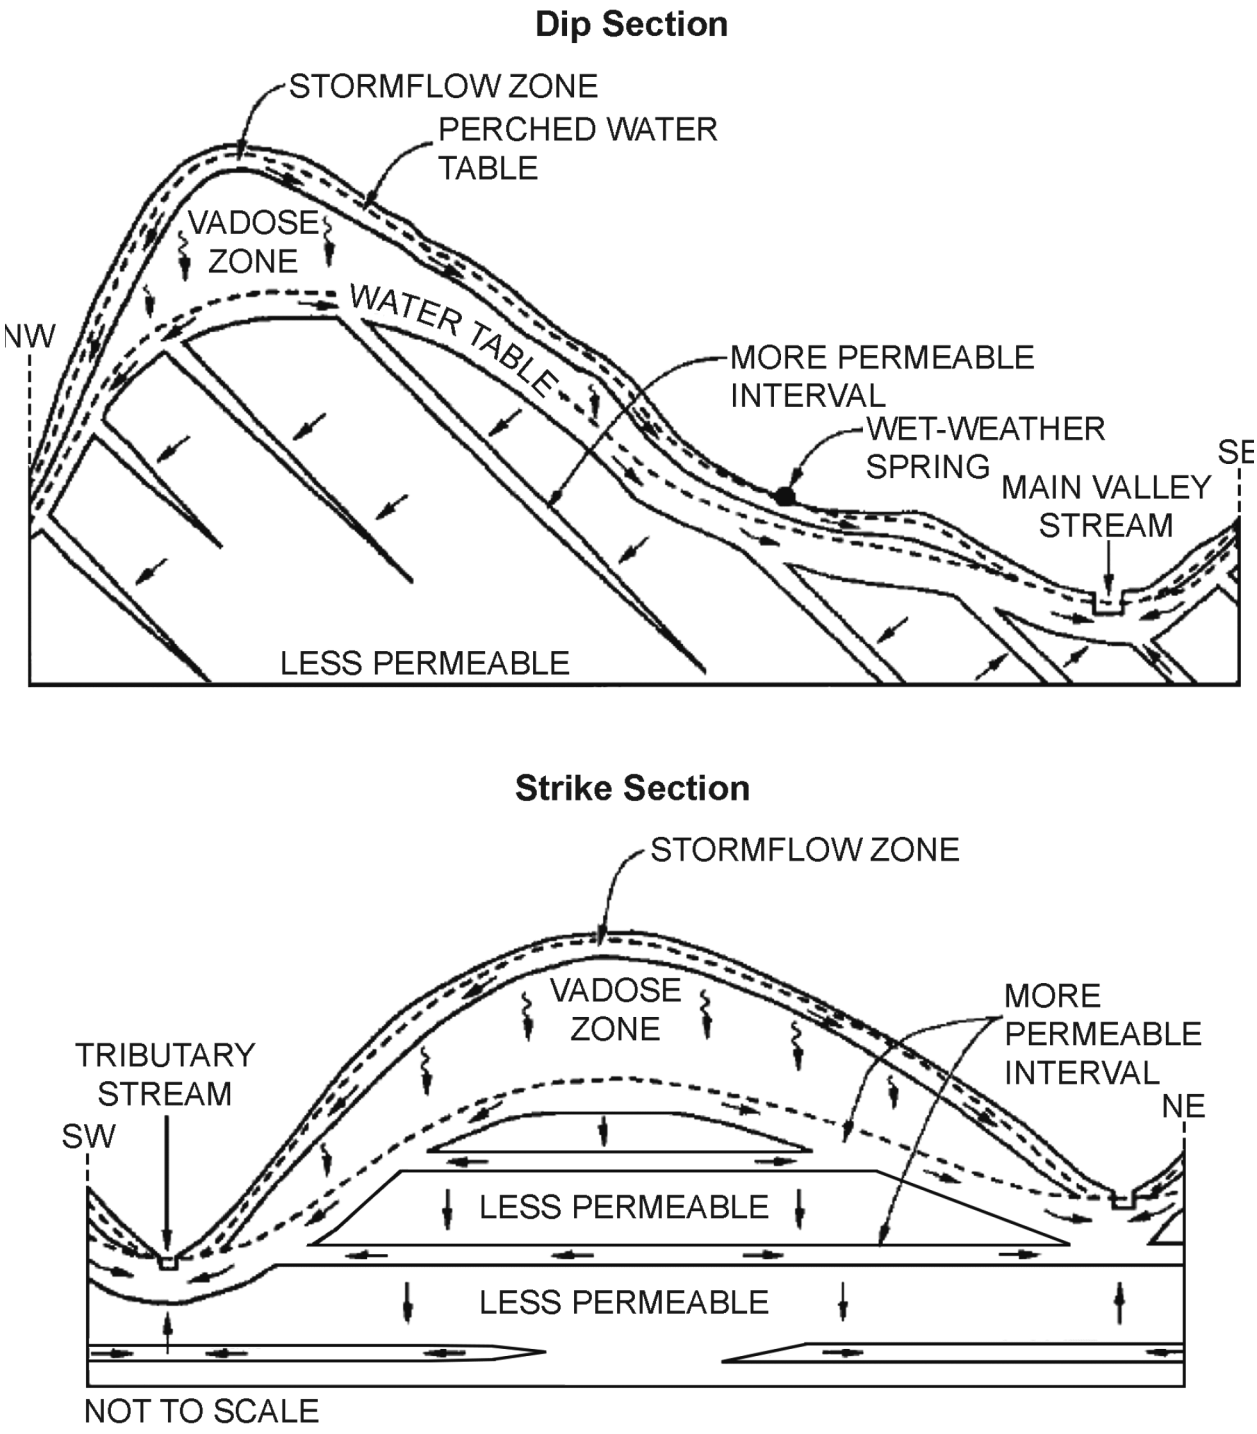

Figure 2.4.13-3R Alternate Conceptual Model for Radionuclide Transport

Source: Adapted from Reference 2.4.13-15

2.4.14 Technical Specifications and Emergency Operation Requirements

Replace the first two sentences of the first paragraph of ESPA SSAR Section 2.4.14 with the following:

The grade elevation of the CRN Site is 814.5 ft NAVD88, and the maximum flood level, as indicated in Subsection 2.4.2.2, is [ ]. The maximum groundwater elevation, as indicated in Subsection 2.4.12, is 814.5 ft NAVD88.

Replace the last sentence of the first paragraph of ESPA SSAR Section 2.4.14 with the following:

Accordingly, there are no requirements for emergency protective measures designed to minimize the impact of hydrology-related events on SC1 facilities, and none are incorporated into the technical specifications or emergency operating procedures.

Replace the last paragraph of ESPA SSAR Section 2.4.14 with the following:

The BWRX-300 plant design does not require use of an SC1 source of cooling water from the Clinch River arm of the Watts Bar Reservoir, and thus related technical specifications or emergency operation requirements are not necessary.

2.5 Geology, Seismology, and Geotechnical Engineering

Section 2.5 of the referenced ESPA SSAR is incorporated by reference with the following supplements.

2.5.1 Geologic Characterization Information

Replace ESPA SSAR Section 2.5.1 with the following:

The geological and seismological information presented in this subsection was developed from a review of previous reports for the proposed Clinch River Breeder Reactor, published geologic literature, and interpretations of data obtained as part of the surface and subsurface field investigations for the 2013 Early Site Permit Application, Site Safety Analysis Report, herein referred to as the 2013 Clinch River Nuclear (CRN) Small Modular Reactor (SMR) investigation and additional site characterization activities in 2023 focused on the planned installation of the GE-Hitachi BWRX-300 SMR to supplement the previous investigations. The investigation data is compiled in a Field Data Report (Reference 2.5.1-341) and the results of analysis of the data are summarized within a Field Data Analysis Report (Reference 2.5.1-340). The results of this investigation and testing campaign conclude that no new geological information was identified at the specific location of Unit 1 at the CRN site, and therefore the conclusions previously presented in ESPA SSAR Section 2.5.1 regarding geotechnical suitability have not changed.

This subsection demonstrates compliance with the requirements of 10 CFR 100.23(c). Information on the geological and seismological characteristics of the Clinch River Nuclear (CRN) site region (200-mile (mi) radius), site vicinity (25-mi radius), site area (5-mi radius), and site location (0.6-mi radius) is presented in this subsection. Subsection 2.5.1.1 describes the geologic and tectonic characteristics of the site region and for stratigraphy, the site vicinity. Subsection 2.5.1.2 describes the geologic and tectonic characteristics of the site vicinity, site area and site location. The geological and seismological information was developed in accordance with RG 1.208 SRP 2.5.1, provides guidance for the development of Subsection 2.5.1.

2.5.1.1 Regional Geology (within the 200-Mile Regional Radius)

2.5.1.1.3.1 Valley and Ridge Province

Renumber Table 2.5.1-1 to Table 2.5.1-1R in the twenty-first paragraph of EPSA SSAR Section 2.5.1.1.3.1.

Renumber Figure 2.5.1-30 to Figure 2.5.1-30R in the twenty-fifth paragraph of EPSA SSAR Section 2.5.1.1.3.1.

2.5.1.1.4.3.1 Current Stress Regime in the Eastern United States

Replace (Figure 2.5.1-21) with (Figure 2.5.1-21 (Sheet 1 of 2) and Figure 2.5.1-21R (Sheet 2 of 2)) in the first, second and fourth paragraphs of EPSA SSAR Section 2.5.1.1.4.3.1.

Renumber Figure 2.5.1-21 (Sheet 2 of 2) to Figure 2.5.1-21R (Sheet 2 of 2) in the third and fifth paragraphs of EPSA SSAR Section 2.5.1.1.4.3.1.

Renumber Figure 2.5.1-21 (Sheet 2 of 2) to Figure 2.5.1-21R (Sheet 2 of 2) in the fourth paragraph of the Potential Driving Mechanism of Stresses in the Eastern United States section of EPSA SSAR Section 2.5.1.1.4.3.1.

2.5.1.1.4.3.2 Distribution of Seismicity: The Eastern Tennessee Seismic Zone

Insert the following after the last paragraph of EPSA SSAR Section 2.5.1.1.4.3.2:

Hatcher et al. (Reference 2.5.1-199) describe possible evidence of multiple paleoearthquakes from paleoseismic trenches and geologic mapping (faults, fluidization structures, bleached or clay-filled fractures, and sand dikes), suggesting the most-recent event may have occurred sometime after approximately 73 ka. Warrell et al. (Reference 2.5.1-200) provides additional information on possible paleoseismic features at Douglas Reservoir. Description of these features is presented in Subsection 2.5.3.2.6.

A conference presentation by Cox et al. (Reference 2.5.1-322) describe evidence for surface faulting with ≥6 ft (2 m) of throw exposed in an alluvial terrace along the Little Tennessee River near Vonore, Tennessee. The age of the terrace is not well constrained, and Cox et al. (Reference 2.5.1-322) do not report evidence for multiple events at this site. In another abstract, Glasbrenner et al. (Reference 2.5.1-323) describe geologic mapping and paleoseismic trenching along the Tellico Reservoir about 22 mi (34 km) southeast of the CRN Site. Based on limited geologic field observations and an apparent seismicity alignment, Cox et al. (Reference 2.5.1-324) and Warrell et al. (Reference 2.5.1-325) propose an active, 70 mi (110-km)-long “Quaternary faulting corridor” (referred to as the Dandridge-Vonore Fault zone; DVFZ) in the ETSZ. They suggest that this Fault corridor may be responsible for at least some of the paleoearthquakes interpreted from exposures near Dandridge, Alcoa, and Vonore, Tennessee. Additional details regarding the proposed DVFZ are provided in a recent field trip guidebook (Reference 2.5.1-326); however, no peer-reviewed publication of these interpretations is available.

Other studies of the ETSZ that post-date development of the CEUS-SSC model have examined the deep crustal structure (Reference 2.5.1-327; Reference 2.5.1-328; Reference 2.5.1-329) and the shallow crustal structure (Reference 2.5.1-330; Reference 2.5.1-331) of the ETSZ. Carpenter et al. (Reference 2.5.1-332) suggests that the **M** 4.2 Perry County, Kentucky, earthquake is related to the ETSZ, thus extending the zone farther north than previously recognized. Yang and Salem (Reference 2.5.1-333) used Permanent Scatterers Synthetic Aperture Radar Interferometry (PSInSAR) data to suggest that land surface deformation may be spatially

associated with areas of higher seismicity rate in eastern Tennessee, but caution that many other processes besides earthquake activity can contribute to surface deformation.

A PSHA performed for the nearby Department of Energy Y-12 National Security Complex in Oak Ridge in 2021 (Reference 2.5.1-334) evaluated this new information on the ETSZ to see if it warranted changes to the CEUS-SSC model. This study developed an additional hazard sensitivity analysis to evaluate the postulated Quaternary faulting corridor associated with the Dandridge-Vonore Fault zone.

The results of DVFZ hazard sensitivity indicate that the DVFZ, as characterized, does not significantly increase hazards at the Y-12 site (Reference 2.5.1-334). The studies further concluded that results from the ongoing paleoseismic studies in the ETSZ are preliminary and do not provide adequate evidence for defining the ages and repeat times of earthquakes and therefore do not provide adequate evidence for defining an RLME seismic source for the ETSZ, and thus no revisions to the CEUS-SSC model are required to account for new data from the ETSZ (Reference 2.5.1-334) (Subsection 2.5.2).

2.5.1.2 Local Geology

Replace EPSA SSAR Section 2.5.1.2 with the following:

The following subsection presents a summary of geologic conditions of the 25-mi (40 km) radius site vicinity, 5-mi (8 km) radius site area, and the 0.6-mi (1 km) radius site location. Site physiography, geomorphology, geologic history, stratigraphy, structural geology, non-seismic geologic hazards, and engineering geology are discussed. The information presented for Clinch River Nuclear Site is based on a review of Clinch River Breeder Reactor Project (CRBRP) reports and documents, Oak Ridge National Lab (ORNL) reports, review of published and unpublished geologic literature, and the results of geotechnical and geologic field investigations conducted in 2013 at the CRN Site for the ESPA and the supplemental site characterization activities for the GE-Hitachi BWRX-300 Small Modular Reactor (SMR) in 2023. Geologic investigations, including field reconnaissance, karst mapping, river-terrace mapping, and geomorphic analyses were complemented with high-resolution LiDAR digital elevation data acquired during the 2013 CRN SMR site investigation. LiDAR coverage encompasses the 5-mi (8 km) radius site area, with pixel resolution of 0.5 ft (15 centimeter (cm)) over a total of 168 sq mi (435 sq km). (Figure 2.5.1-23). Geologic field reconnaissance way points are located on Figure 2.5.1-25.

2.5.1.2.3 Local Stratigraphy and Lithology

Replace EPSA SSAR Section 2.5.1.2.3 with the following:

The following summary of the stratigraphy and lithology within the CRN Site (Figure 2.5.1-29R) is largely based on the description of the geologic units presented in Hatcher et al. (Reference 2.5.1-9) and Lee and Ketelle (Reference 2.5.1-110), and from site-specific data generated as part of the 2013 CRN SMR site subsurface investigation (Reference 2.5.1-214) and

the 2023 supplemental site characterization activities for the GE-Hitachi BWRX-300 SMR (Reference 2.5.1-341).

2.5.1.2.3.1 Stratigraphic Nomenclature Approach

Replace the third sentence of the first paragraph of the EPSA SSAR Section 2.5.1.2.3.1 with the following:

Lee and Ketelle (Reference 2.5.1-110) completed a study at the ORNL (X-10 Facility) that provides an analog to the CRN Site as it is located directly along strike of the section investigated in 2013 for the CRN SMR Project and 2023 for the BWRX-300 SMR, approximately 4.5-mi (7.2 km) to the northeast.

Replace the third sentence of the second paragraph of the EPSA SSAR Section 2.5.1.2.3.1 with the following:

The 2013 CRN SMR investigation adopted the Hatcher et al.(Reference 2.5.1-9) stratigraphic nomenclature. This nomenclature was carried forward for the 2023 BWRX-300 SMR investigation.

Renumber Table 2.5.1-1 to Table 2.5.1-1R in the third paragraph of EPSA SSAR Section 2.5.1.2.3.1.

Replace the fourth sentence of the third paragraph of the EPSA SSAR Section 2.5.1.2.3.1 with the following:

In general, unit boundaries correlate to distinctive changes in the overall gamma and/or conductivity data observed in the borings logged in 2013 for the CRN SMR Project and 2023 for the BWRX-300 SMR.

2.5.1.2.3.2 Local Stratigraphy

Renumber Figure 2.5.1-30 to Figure 2.5.1-30R in the first paragraph of EPSA SSAR Section 2.5.1.2.3.2.

Replace the last two sentences of the first paragraph of the EPSA SSAR Section 2.5.1.2.3.2 with the following:

Rocks of the Rome Formation do not outcrop at the site, but they were encountered by two 2013 CRN SMR subsurface investigation boreholes. The 2013 CRN SMR subsurface investigation borehole locations and the location of the geologic cross-section depicted in Figure 2.5.1-30R are shown on Figure 2.5.1-31R.

Replace the first sentence of the second paragraph of the EPSA SSAR Section 2.5.1.2.3.2 with the following:

A total of 82 geotechnical boreholes (76 in rock) were drilled on the CRN Site as part of the 2013 CRN SMR investigation (Reference 2.5.1-214) and 27 geotechnical boreholes (16 in rock) were drilled on the CRN Site as part of the 2023 BWRX-300 SMR investigation (Reference 2.5.1-341).

Replace the third sentence of the second paragraph of the EPSA SSAR Section 2.5.1.2.3.2 with the following:

The Witten Formation, which stratigraphically lies between the older Bowen Formation and the younger Moccasin Formation, was not encountered during the 2013 CRN SMR subsurface investigation drilling program but was encountered in the 2023 BWRX-300 SMR investigation.

Replace Table 2.5.1-2 with Table 2.5.1-2 (Sheets 1-3 of 4) and Table 2.5.1-2R (Sheet 4 of 4) in the second paragraph of EPSA SSAR Section 2.5.1.2.3.2.

Renumber Table 2.5.1-3 with Table 2.5.1-3R in the second paragraph of EPSA SSAR Section 2.5.1.2.3.2.

2.5.1.2.3.3 Local Lithology

Replace the first paragraph of EPSA SSAR Section 2.5.1.2.3.3 with the following:

From oldest to youngest, the following descriptions of the bedrock units encountered at the CRN Site are based on an assessment of the 2013 CRN SMR subsurface investigation boring logs, geologic mapping, and previous investigations (Reference 2.5.1-214). Descriptions of the bedrock units encountered in the 2023 BWRX-300 SMR subsurface investigation are discussed in Reference 2.5.1-340. Lithologic descriptions of the CRN Site stratigraphic units are supplemented with laboratory analytical data, downhole geophysical data, and petrographic data generated during the 2013 CRN SMR and 2023 BWRX-300 SMR subsurface investigations, as available (Reference 2.5.1-214; Reference 2.5.1-341). Definitions of lithologic adjectives and modifiers used in the 2013 descriptions below are provided in Table 2.5.1-4.

Renumber Table 2.5.1-1 to Table 2.5.1-1R in the first paragraph of the Knox Group – Newala Formation – Kingsport Formation/Mascot Dolomite subsection of EPSA SSAR Section 2.5.1.2.3.3.

Renumber Table 2.5.1-3 to Table 2.5.1-3R in the first paragraph of the Chickamauga Group – Blackford Formation subsection of EPSA SSAR Section 2.5.1.2.3.3.

Renumber Table 2.5.1-3 to Table 2.5.1-3R in the first paragraph of the Chickamauga Group – Eidson Member of the Lincolnshire Formation subsection of EPSA SSAR Section 2.5.1.2.3.3.

Renumber Table 2.5.1-3 to Table 2.5.1-3R in the first paragraph of the Chickamauga Group – Fleanor Member of the Lincolnshire Formation subsection of EPSA SSAR Section 2.5.1.2.3.3.

Insert the following after the last paragraph of the Chickamauga Group – Fleanor Member of the Lincolnshire Formation subsection of ESPA SSAR Section 2.5.1.2.3.3.

Descriptions of the Fleanor Member from the 2023 BWRX-300 SMR subsurface investigation are presented in Reference 2.5.1-340.

Renumber Table 2.5.1-3 to Table 2.5.1-3R in the first paragraph of the Chickamauga Group – Rockdell Formation subsection of EPSA SSAR Section 2.5.1.2.3.3.

Insert the following after the last paragraph of the Chickamauga Group – Rockdell Formation subsection of ESPA SSAR Section 2.5.1.2.3.3.

Descriptions of the Rockdell Formation (Unit C and D members) from the 2023 BWRX-300 SMR subsurface investigation are presented in Reference 2.5.1-340.

Renumber Table 2.5.1-3 to Table 2.5.1-3R in the first paragraph of the Chickamauga Group – Benbolt Formation subsection of EPSA SSAR Section 2.5.1.2.3.3.

Insert the following after the last paragraph of the Chickamauga Group – Benbolt Formation subsection of ESPA SSAR Section 2.5.1.2.3.3.

Descriptions of the Benbolt Formation from the 2023 BWRX-300 SMR subsurface investigation are presented in Reference 2.5.1-340.

Renumber Table 2.5.1-1 to Table 2.5.1-1R in the second paragraph of the Chickamauga Group – Bowen Formation subsection of EPSA SSAR Section 2.5.1.2.3.3.

Insert the following after the last paragraph of the Chickamauga Group – Bowen Formation subsection of ESPA SSAR Section 2.5.1.2.3.3.

Descriptions of the Bowen Formation from the 2023 BWRX-300 SMR subsurface investigation are presented in Reference 2.5.1-340.

Replace the first paragraph of the Chickamauga Group – Witten Formation subsection of ESPA SSAR Section 2.5.1.2.3.3 with the following:

The Witten Formation was not encountered during the 2013 CRN SMR subsurface investigation drilling program but was encountered in the 2023 BWRX-300 SMR drilling program in U1-B15 (Figure 2.5.1-30R). Descriptions of the Witten Formation from the 2023 investigation are presented in Reference 2.5.1-340. Alternatively, lithologic descriptions from Lee and Ketelle (Reference 2.5.1-110) and Hatcher et al. (Reference 2.5.1-9) are summarized here.

2.5.1.2.3.4 Karst Evaluation

Replace the first sentence of the first paragraph of ESPA SSAR Section 2.5.1.2.3.4 with the following:

A review of the cavity data from the 2013 CRN SMR and CRBRP Site drilling programs reveal several trends illustrated in Figures 2.5.1-75 through 2.5.1-77.

Replace the third and fourth sentences of the first paragraph of ESPA SSAR Section 2.5.1.2.3.4 with the following:

For this analysis, karst cavity data were partitioned into three elevation intervals. Intervals were as follows: (1) above the 2013 CRN SMR proposed plant grade of elevation 821 ft NAVD88; (2) between elevations 821 ft NAVD88 and 740 ft NAVD88, the shallowest embedment depth considered for the 2013 CRN SMR plant and also the Watts Bar Reservoir pool elevation; and (3) lower than elevation 740 ft NAVD88.

Replace the first sentence of the second paragraph of ESPA SSAR Section 2.5.1.2.3.4 with the following:

The cavities that occur below the current Watts Bar Reservoir elevation of 740 ft NAVD88, which is the current Watts Bar Reservoir elevation as well as the shallowest embedment depth considered in the 2013 CRN SMR investigation, reflect dominantly phreatic development below the water table.

Replace the fifth sentence of the third paragraph of ESPA SSAR Section 2.5.1.2.3.4 with the following:

Additionally, carbonate contents were determined from rock core samples during the 2013 CRN SMR subsurface investigation (Figure 2.5.1-49).

Replace the fourth paragraph of ESPA SSAR Section 2.5.1.2.3.4 with the following:

The spatial distribution of cavities is consistent with the trends discussed above. A map of boreholes indicating the presence and elevation interval of cavities is presented in Figure 2.5.1-79. Several boreholes within the Rockdell Formation in the south-center of the previously planned CRN SMR power block area exhibit cavities in the middle and lower elevation intervals. The footprint of the BWRX-300 lies within the footprint of Location A of the previously planned CRN SMR. The boreholes and cavities occur along strike with bedding. However, elevations of individual cavities within this cluster do not appear to correlate directly. Boreholes B-144 and B-145, spaced approximately 33 ft apart, have cavities at elevation 781 ft NAVD88, although connectivity between cavities is uncertain.

Contrary to previous drilling investigations at the CRN Site in which many dissolution features larger than 0.1 ft were described, only two (2) of such cavity size were described in cored samples recovered and described in the 2023 CRN Site investigation. One cavity was described in U1-B16 at a depth of 29.4 ft in the rocks of the Witten Formation, while the other cavity was

interpreted as a 0.9 ft maximum size based on core loss in U1-B05 between depths of 145.4 and 150.4 ft, within rocks of the Rockdell Formation (Reference 2.5.1-340). This fact highlights the scarcity of karst in the units below the Unit 1 location.

2.5.1.2.3.5 Unconsolidated Soils/Fill/Terraces

Replace the first paragraph of ESPA SSAR Section 2.5.1.2.3.5 with the following:

Residual soils and backfill encountered in the 2013 CRN SMR subsurface investigation boreholes are discussed in Subsection 2.5.4, while those encountered in the 2023 BWRX-300 SMR supplemental investigation boreholes are discussed in the Reference 2.5.1-340.

2.5.1.2.4.2.1 Geophysical Data

Insert the following after the first paragraph of ESPA SSAR Section 2.5.1.2.4.2.1:

Surface Analysis of Seismic Waves (SASW) was conducted at the CRN site to support the 2023 BWRX-300 SMR subsurface investigation (Figure 2.5.1-29R) (Reference 2.5.1-341). The primary objectives of the SASW survey were to evaluate the shear wave velocity profile of the subsurface at CRN Site. The shear wave velocity profiles from the SASW survey are discussed in Reference 2.5.1-340.

2.5.1.2.4.2.1.1 Seismic Reflection Data

Renumber Figure 2.5.1-30 to Figure 2.5.1-30R in the seventh paragraph of EPSA SSAR Section 2.5.1.2.4.2.1.1.

Add new Section 2.5.1.2.4.2.1.3:

2.5.1.2.4.2.1.3 Surface Analysis of Seismic Waves

Five SASW lines were acquired at the CRN Site during the 2023 BWRX-300 SMR subsurface investigation (Figure 2.5.1-29R) (Reference 2.5.1-341). SASW field testing involves generating surface waves at one location on the exposed material surface and simultaneously measuring the motions perpendicular to the surface created by the passage of surface waves between multiple pairs of surface receivers. Analysis of the SASW survey is discussed in Reference 2.5.1-340.

2.5.1.2.4.2.3 Copper Creek Fault

Renumber Figure 2.5.1-30 to Figure 2.5.1-30R in the second paragraph of EPSA SSAR Section 2.5.1.2.4.2.3.

2.5.1.2.4.3.2 Bedding

Renumber Figure 2.5.1-30 to Figure 2.5.1-30R in the second paragraph of EPSA SSAR Section 2.5.1.2.4.3.2.

Insert the following after the last paragraph of ESPA SSAR Section 2.5.1.2.4.3.2:

The 2023 BWRX-300 SMR subsurface investigation ATV data reveals incredibly consistent bedding measurements (n=855) between all boreholes and stratigraphic units encountered. The strike is predominantly between 50- and 70-degrees azimuth and a mean of 61.3 degrees, while the dips predominantly range between 140- and 160-degrees azimuth with a mean of 151.3 degrees. The median orientation of all of the bedding measurements is 060/33, which is highly concordant with the 2013 mapping and ATV data, all having mean dips of 33 degrees. Geologic cross-sections using subsurface contacts observed in boreholes (Figure 2.5.1-30R) also indicate bedding dips are consistent across the site (Reference 2.5.1-340).

2.5.1.2.4.3.3 Fractures

Replace the second sentence of the fifth paragraph of ESPA SSAR Section 2.5.1.2.4.3.3 with the following:

In the 2013 CRN SMR investigation, fracture surfaces were defined as planar, discontinuous or irregular, while fracture thickness is described as hairline or open, based on whether there was observed material loss along the joint surface.

Insert the following after the last paragraph of ESPA SSAR Section 2.5.1.2.4.3.3:

The 2023 supplementary investigation ATV data are broadly consistent with that of the 2013 data, though with a much smaller dataset due to the lesser number of ATV data collected. The strike of the 2023 fractures ranges predominantly between 220- and 250-degrees azimuth with a mean of 234.4 degrees, while the dips predominantly range between 310- and 340-degrees azimuth with a mean of 324.4 degrees. The two dominant sets in the 2023 fracture data are consistent with the dominant sets in the 2013 dataset in that both are oriented parallel to strike. While the most dominant set is most consistent (mean orientation of 234/56), the subordinate set dips SE, close to bedding orientation, but has overall a steeper average dip and slightly rotated strike (mean orientation of 075/54) than the secondary set in the 2013 data. Greater details of the 2023 BWRX-300 SMR subsurface investigation fracture sets and comparison to early investigation data are discussed in Reference 2.5.1-340.

2.5.1.2.4.3.4 Shear-Fracture Zones

Replace the first sentence of the fifth paragraph of ESPA SSAR Section 2.5.1.2.4.3.4 with the following:

As noted above, additional shear-fracture zone features were also observed up-section in boreholes during the 2013 CRN SMR investigation further to the southeast within the Benbolt and Rockdell Formations (Figure 2.5.1-65).

Insert the following after the fifth paragraph of ESPA SSAR Section 2.5.1.2.4.3.4:

Similar healed shear-fracture zones were identified during the 2023 field investigation located and characterized in only 8 of the 16 rock core boreholes drilled. These healed shear-fractures were identified in depth intervals corresponding to the Rockdell Formation (25 intervals out of 28 described intervals), the Benbolt Formation (2 intervals) and one occurrence in the recently first-time drilled Witten Formation. The presence of these healed shear-fractures is not observed to be laterally continuous zones through multiple borings with shear-fracture zone features in the Benbolt only occurring in the upper strata of the formation, while those identified in the Rockdell Formation appear to comprise different localized zones all throughout the formation thickness. The only occurrence in the Witten Formation was described in the bottom third of the formation. These features as identified in the 2023 subsurface investigation are discussed in more detail in Reference 2.5.1-340.

Insert the following after the last paragraph of ESPA SSAR Section 2.5.1.2.4.3.4:

Based on the determined age of the shear fracture zone features during Alleghenian shortening, they are not considered an active hazard to the CRN site. It is furthermore suggested that the previously established term “shear-fracture” for these features is a misnomer within the site, as they are not traditional tectonic shear zones. Regardless, they are factors in the foundation rock mass assessment for bearing capacity and further characterization of such features, if identified, shall be performed via geologic mapping during excavation for the power block area.

2.5.1.2.4.4 Characterization of Alleghenian Foreland Fold-Thrust Structures

Replace the first sentence of the fourth paragraph of ESPA SSAR Section 2.5.1.2.4.4 with the following:

As discussed in Subsection 2.5.1.2.4.3.4, zones of localized deformation termed shear-fracture zones were encountered in borings related to the CRBRP investigation (References 2.5.1-100, 2.5.1-238), the 2013 CRN SMR Site investigation (Reference 2.5.1-214) and the 2023 BWRX-300 SMR supplemental investigation (Reference 2.5.1-340).

2.5.1.2.5.1.2 Karst Processes and Features at the Clinch River Nuclear Site

Replace the last two sentences of the first paragraph of the Karst Features Observed in Boreholes subsection of ESPA SSAR Section 2.5.1.2.5.1.2 with the following:

Due to grading of the site during the 1980s, the irregular bedrock surface is best expressed in the CRBRP soil borings and in the 2013 CRN SMR Site soil borings outside the graded areas. In a few of these 2013 CRN SMR Site soil borings, blow counts are observed to decrease with depth consistent with dissolution of the rockhead and loss of the deepest horizons of the soil into slots and cavities in the rock.

Replace the second paragraph of the Karst Features Observed in Boreholes subsection of ESPA SSAR Section 2.5.1.2.5.1.2 with the following:

Cavities, both open and clay-filled, were encountered in rock core borings drilled at the site. A total of 240 cavities, defined as being at least 0.1 ft (3 cm) in height in the core, were logged in rock core borings, including borings from the CRBRP drilling program (Reference 2.5.1-100), the 2013 CRN SMR drilling program (Table 2.5.1-11 (Sheets 1-6 of 7) and Table 2.5.1-11R (Sheet 7 of 7) and the 2023 BWRX-300 SMR drilling program. However, only 2 of those cavities were identified during the 2023 program. Of the 196 rock core borings drilled at the site (104 for the CRBRP, 76 for the 2013 CRN SMR investigation and 16 for the 2023 BWRX-300 SMR supplemental investigation), 77 borings, or 39 percent, encountered one or more cavities (Table 2.5.1-11 (Sheets 1-6 of 7) and Table 2.5.1-11R (Sheet 7 of 7)). This number should be considered a minimum as not all possible solution features were logged as cavities. The Clinch River Nuclear Site CRBRP borings encountered clay intervals up to 8 ft (2.4 m) thick in five borings (Reference 2.5.1-100). The clay was described as similar to the overburden residual soils and interpreted to represent in situ weathering. Alternatively, these intervals could represent cavities that have been filled with soil washed in from above. Weathered and fractured zones were encountered in some 2013 CRN SMR and 2023 BWRX-300 SMR borings where core losses of 1 to 3 ft (0.3 to 1 m) took place. Dissolution is likely to have played a role in the weathering of these zones, as the lithologies are calcareous.

Replace Table 2.5.1-11 with Table 2.5.1-11 (Sheets 1-6 of 7) and Table 2.5.1-11R (Sheet 7 of 7) in the third paragraph of the Karst Features Observed in Boreholes section of EPSA SSAR Section 2.5.1.2.5.1.2.

2.5.1.2.5.1.3 Potential Karst Hazard at the CRN Site

Replace Table 2.5.1-11 with Table 2.5.1-11 (Sheets 1-6 of 7) and Table 2.5.1-11R (Sheet 7 of 7) in the first paragraph of EPSA SSAR Section 2.5.1.2.5.1.3.

Replace the fifth sentence of the first paragraph of ESPA SSAR Section 2.5.1.2.5.1.3 with the following:

A complete understanding of the extent and spatial distribution of these cavities or other potential karst cavities contains some uncertainty; however, the significant amount of data collected at the

CRN Site during the 2013 CRN SMR and 2023 BWRX-300 SMR investigations, as well as during past investigations and excavations, provides a comprehensive understanding of the karst setting within approximately 300 ft (91.4 m) of the ground surface.

2.5.1.2.5.2 Other Local Geologic Hazards

Replace the first sentence of the fifth paragraph of ESPA SSAR Section 2.5.1.2.5.2 with the following:

Underground mining and petroleum and gas extraction have not taken place at the site, however naturally occurring hydrocarbon fluids have been identified in the subsurface at the site (Subsection 2.5.1.2.5.2.1).

Add new Section 2.5.1.2.5.2.1:

2.5.1.2.5.2.1 Subsurface Petroleum Feature

Groundwater observation wells OW-422U, OW-422L, and OW-422D were installed on the southeast portion of the CRN Property as part of the 2013 geotechnical exploration, with total approximate termination depths of 44 feet below ground surface (bgs), 181 feet bgs, and 330 feet bgs, respectively (Reference 2.5.1-339). During the development of groundwater observation well OW-422L, the presence of petroleum was detected within the well, exceeding two feet in thickness. The groundwater and light non-aqueous phase liquids (LNAPL) from the well were sampled and analyzed by TVA, Department of Energy (DOE), and the TDEC personnel with the analytical results being reported to TDEC in Nashville, Tennessee (Reference 2.5.1-339). Due to this discovery, alternate borings were drilled to replace OW-422U, OW-422D, and OW-422L for geotechnical considerations.

The initial laboratory data from well OW-422L reportedly identified gasoline- and diesel-range organic compounds (GRO and DRO) including benzene, ethylbenzene, toluene, 1,2,4 trimethylbenzene, and xylenes, as well as other volatile organic compounds (VOCs) including acetone, carbon disulfide, chloroform, and isopropyl benzene (Reference 2.5.1-339). Subsequent aquifer pump tests were performed for all three wells in 2014 which concluded that groundwater elevation measurements collected indicated a “direct and instantaneous” response to precipitation received by the site with respect to changes in groundwater elevations (Reference 2.5.1-339).

Later testing of the groundwater and petroleum product in all three wells was performed in 2022 for total petroleum hydrocarbons (TPH) using Gas Chromatography-Flame Ionization Detection (GC-FID) and for chemical analysis of VOCs to provide current chemical laboratory data for each well for comparison to historical VOC laboratory results. The data was further evaluated by comparing the sample chromatogram in conjunction with a chromatogram of a normal alkane series generated with the same chromatographic conditions (Reference 2.5.1-339). An independent review of the supplemental chemical data was then performed to determine the source (refined or naturally occurring crude oil) of the petroleum present in OW-422L.

The results of the analysis indicate that the OW-422L (LNAPL and water) samples did not exhibit enrichment of specific analytes such as naphthalenes and mono-aromatics (benzene, toluene, ethylbenzene, and xylene (BTEX) in quantities consistent with those in refined petroleum product, nor did the samples exhibit olefins constituents in quantities or contain additive compounds consistent with refined petroleum products (Reference 2.5.1-339). Further comparison revealed the absence of 2-methyl anthracene (2-MA) typically produced during thermal or catalytic cracking (refining) of crude oils. The comparison between the LNAPL and the groundwater collected from well OW-422L revealed similar analytes (n-paraffins and alkylcyclohexanes) indicating the petroleum is consistent with immature to medium maturity crude oil feedstock (Reference 2.5.1-339). Laboratory analytical results for groundwater from observation wells OW-422U and OW-422D did not report concentrations of VOCs above laboratory reported detection levels.

These results indicate that the petroleum product in well OW-422L is a naturally occurring hydrocarbon product. Furthermore, since the other two wells in the cluster do not seem to have any similar product, it can be speculated that the product is likely specific to the screened in interval in well OW-422L which is in the lower portion of the Benbolt Formation. The occurrence of this naturally occurring petroleum product at the location near the base of the Benbolt formation could only be speculated upon. It could potentially be due to this stratigraphic interval being a reservoir with petroleum product that migrated from greater depths, or it could potentially be that this interval is the source as well as the reservoir.

There are two main petroleum source systems within Tennessee, which are the Knox/Middle Ordovician System and the Devonian/Mississippian System (Reference 2.5.1-335). Considering the site area is underlain by a repeated section of Cambrian to Middle Ordovician strata, the Devonian/Mississippian source can be ruled out. Within the Knox/Middle Ordovician petroleum system are three main hydrocarbon reservoirs, which are the Cambro-Ordovician Knox Group, the Nashville Group, and the Stones River Group (Reference 2.5.1-335).

The post-Knox unconformity is a known oil reservoir that has been explored and exploited throughout the Appalachian Basin (Reference 2.5.1-336). This contact occurs at the site at the boundary of the Newala and Blackford Formations that crop out approximately 1,500 ft to the northwest of the site center. The Knox unconformity occurs at an interpreted depth of approximately 1,000 ft below the site, or an elevation of -300 ft msl. A review of oil well permits was completed within Roane County and surrounding counties (Reference 2.5.1-338). There are no oil wells within the site area. Within the Valley and Ridge physiographic province, there is one Knox oil well in Reigs County to the Southwest of the site, one in Loudon County to the southeast of the site, and three within Anderson County northeast of the site.

The middle Ordovician Nashville Group and Stones River Group are geologically equivalent to the Trenton Group and Black River Group (Reference 2.5.1-335) that have been explored significantly in the northern Appalachian Basin (Reference 2.5.1-337). Research completed by Hatcher et al. (Reference 2.5.1-9) indicate that the Nashville Group and Stones River Group are part of the Chickamauga Supergroup, which contains the Benbolt Formation where OWL-422 was screened. Analysis of oil well permit data (Reference 2.5.1-338) reveals that there are no

Chickamauga Group oil wells within the site area, or within the Valley and Ridge province portions of Anderson, Loudon, Meigs, or McMinn Counties.

The 2023 supplemental site investigation for the BWRX-300 technology contained provisions to further investigate the potential presence of the petroleum product within samples collected from this stratigraphic depth. However, the OW-422 well cluster was grouted shut and closed in early 2023, prior to the supplemental site investigation, ruling out observation of any potential petroleum product activity in OW-422L. The 2023 supplemental site investigation for the BWRX-300 employed a process for screening for potential naturally occurring crude in the subsurface.

The borings were screened at specified intervals during the drilling and rock core samples were collected and tested for VOCs using a flame ionization detector (FID) as well as for methane, hydrogen sulfide, and oxygen levels using a 4-gas meter. The screening was conducted at the top of the drill tool string and in the work area of the drill crew and recorded by the Rig Geologist/Geotechnical Engineer. Rig personnel also made a point to observe the return water for sheen and coloring that may be indicative of the presence of crude oil. If FID screening levels exceed 350 parts per million (ppm); and/or methane exceeds the upper explosive limit (UEL) of 17% or hydrogen sulfide exceeds 44%; and/or oxygen is below 19%; work was stopped at the drill depth where the readings were recorded, and appropriate actions were taken to address the issue.

Petroleum was visually observed within the recovered core samples at several borings (Reference 2.5.1-340). Table 2.5.1-20 summarizes the borings in which petroleum was observed. The petroleum observed in the rock core was screened using the FID and the depth interval and screening values were documented on the boring log. Additional readings were collected at the top of the drill string at selected depths and were recorded in the boring log.

The only instance of elevated FID readings exceeding the 350 ppm threshold set for the project was when naturally occurring petroleum (crude) was encountered. This was in boring U1-B02 within the rock core at a depth of approximately 320.0 feet below ground surface (elevation 480.3 ft). The FID reading collected from the top of the drill string when the boring reached 323.0 feet was 60.9 parts per million (ppm). When the boring had been drilled to a depth of 343.0 feet an FID reading was collected from the top of the drill string which indicated a concentration of 436.0 ppm.

Additional readings were collected over time from the drill string and within the work area. The 4-gas meter did not detect any exceedances of the UEL or reduction of oxygen within the work area. The FID readings reduced to safe levels over time, and drilling resumed at the boring. The FID readings in Boring U1-B02 from 343.0 feet to the termination of the boring at 445.1 feet ranged from 10.7 to 255.0 ppm. Boring U1-B02 was the only boring to detect levels of VOCs which exceeded the site safety threshold values.

The other instances of visually observed crude within the recovered core samples (Table 2.5.1-20) did not result in elevated FID readings exceeding the 350 ppm threshold. During the performance of the subsurface investigation there were no detections at any of the borings of

concentrations which exceeded the UEL for methane (17%), and/or hydrogen sulfide (44%), and/or oxygen below 19%.

Except for a heavy oil sample observed in a fracture in U1-B15 (115.5 to 115.9 ft-BGS) all observed petroleum identified within the recovered core samples (Table 2.5.1-20) show similar characteristics to the one recovered and described in the OW-422 well cluster. All presence of petroleum in boreholes U1-B01, U1-B02, U1-B03 and U1-B05 was identified in rocks of the Rockdell Formation, or in the base of the Benbolt Formation right in the contact or near the contact with the underlying Rockdell Formation. Petroleum described in U1-B08 was identified in rocks of the Benbolt Formation. The two intervals where petroleum was identified in U1-B15 were described in rocks of the Witten Formation.

Based on the depth of the potential reservoir layer below the ground surface in OW-422L (screened between El 643-623), the stratigraphic interval exists below the bottom of the proposed foundation elevation along strike from the well. However, the potential exists for migration of the petroleum product, either stratigraphically up dip into the excavation or along fractures or karst features, to some other part of the excavation.

The potential presence of the natural occurring crude is a mitigatable issue for construction or operation of the SMR as the foundation concrete that will be placed along the excavation surface of the reactor vessel should be expected to form a barrier preventing any potential amount of natural crude from entering into the foundation of the proposed SMR during operation.

The possibility of natural crude is merely a condition that should be planned and accounted for during foundation excavation and construction of the plant. A contingency plan should be formed for the possibility of petroleum seepage during excavation that establishes protocols if the presence is identified. Monitoring the fluids transferred through the dewatering system for the presence of any hydrocarbon contamination would be a practical detection method. Ultimately, consultation with the excavation and blasting subcontractors and all involved parties will need to take place to determine a consensus remedy and path forward if contamination is detected.

2.5.1.2.6.1 Summary of Subsurface Conditions

Insert the following after the third sentence of the first paragraph of ESPA SSAR Section 2.5.1.2.6.1:

A supplemental site investigation in 2023 was performed for the subsequently planned BWRX-300 SMR technology. Soil boring and rock coring logs are presented in Appendix III to Reference 2.5.1-341.

Replace the second sentence of the second paragraph of ESPA SSAR Section 2.5.1.2.6.1 with the following:

The stratigraphic units underlying the BWRX-300 power block area, from lower to upper units are predominantly the Lincolnshire Formation (Fleanor Member), and Rockdell and Benbolt Formations belonging to the Chickamauga Group (Appendix B.1 Reference 2.5.1-214 and Appendix III to Reference 2.5.1-341).

Renumber Figure 2.5.1-30 to Figure 2.5.1-30R in the second paragraph of EPSA SSAR Section 2.5.1.2.6.1.

Replace the second sentence of the third paragraph of ESPA SSAR Section 2.5.1.2.6.1 with the following:

Information on the orientation of the bedding planes and fractures is from downhole ATV logging performed at the site in 27 borings during the 2013 CRN SMR site investigation and 8 borings during the 2023 BWRX-300 SMR subsurface investigation.

Replace the fourth paragraph of ESPA SSAR Section 2.5.1.2.6.1 with the following:

The footprint of the power block area of the currently planned BWRX-300 SMR technology is shown on Figure 2.5.1-31R. The final grade of the currently planned BWRX-300 SMR technology is expected to be 814.5 ft (248 m) NAVD88 and the foundation level within the power block area is expected to be approximately 115 ft (35.2 m) below the planned final grade (El. 699.5 ft (213 m) NAVD88). The supplemental site-specific subsurface investigation and testing program for the 2023 BWRX-300 technology) was conducted to supplement the CPA for the selected GEH BWRX-300 technology. This additional testing and exploration program was done to ensure that the site-specific safety requirements were met, and potential hazards were identified and addressed before construction begins. The testing also provides additional data to supplement the existing information and datasets to inform any necessary modifications to the design or operational procedures. The 2023 CRN Site investigation dataset is presented in Reference 2.5.1-341 with analysis of the data presented in Reference 2.5.1-340 which describes how the existing data is bounding to the previous datasets.

2.5.1.2.6.2 Rock Mass Characterization

Renumber Figure 2.5.1-31 to Figure 2.5.1-31R in the third paragraph of EPSA SSAR Section 2.5.1.2.6.2.

Insert the following after first paragraph of the Fleanor Member subsection of ESPA SSAR Section 2.5.1.2.6.2:

Parallel GSI calculations were performed on the 2023 BWRX-300 SMR investigation boring log fracture dataset for all rock formations encountered in the 2023 CRN site investigation, using essentially the same methods as the 2013 investigation calculation. Generally, the GSI ratings for all formations at the CRN Site are between 60 and 85, which correspond with very block to blocky rock mass structure. These structures are described in Reference 2.5.1-265 as interlocked, partially disturbed to undisturbed rock masses, made up of cubical to angular blocks formed by 3 or more joint sets. These structures are of the highest rated rock structures for stability. When comparing the 2013 and 2023 investigations, GSI calculations produced for the major formations encountered have almost identical results for the typical GSI range. The details of the 2023 calculation are presented in Reference 2.5.1-340.

Replace the fourth paragraph of Newala Formation subsection of ESPA SSAR Section 2.5.1.2.6.2 with the following:

The GSI classifications of the stratigraphic units are based on a select number of 100-, 200- and 400-series borings drilled at the CRN Site.

2.5.1.2.6.3 Fracture Zones

Replace the first sentence of the first paragraph of ESPA SSAR Section 2.5.1.2.6.3 with the following:

Borings drilled during the 2013 CRN SMR and 2023 BWRX-300 SMR investigations (Appendix B.1 Reference 2.5.1-214; Appendix III Reference 2.5.1-341) indicate the presence of weathered or fracture zones within the stratigraphic units.

Replace the last sentence of the first paragraph of ESPA SSAR Section 2.5.1.2.6.3 with the following:

The 2013 CRN SMR site investigation data indicates that few bedding fractures have weathering or weakening below the power block foundation level.

Replace the fourth paragraph of ESPA SSAR Section 2.5.1.2.6.3 with the following:

Characterization of the weathered or fracture zones is based on the 100- and 200-series borings drilled at the CRN Site during the 2013 CRN SMR investigation. Further evaluation of these zones may be required, when the excavation method has been finalized.

2.5.1.2.6.4 Deformational Zones

Replace the first sentence of the first paragraph of ESPA SSAR Section 2.5.1.2.6.4 with the following:

Borings drilled at during the 2013 CRN SMR and 2023 BWRX-300 SMR investigations encountered what is termed shear-fracture zones, which represent localized zones of strain accommodated via pressure solution with limited cataclasis (Subsection 2.5.1.2.4.3.4).

Insert the following after the second paragraph of ESPA SSAR Section 2.5.1.2.6.4:

A discussion of the shear-fracture zones (greater than or equal to approximately 0.9 ft (27 cm) thick (apparent thickness along boring axis)) encountered in the borings drilled in 2023 at the CRN Site are contained in Reference 2.5.1-340.

Replace the fifth paragraph of ESPA SSAR Section 2.5.1.2.6.4 with the following:

Characterization of the shear-fracture zones is based on the 100-, 200-, and 400-series borings drilled at the CRN Site during the 2013 CRN SMR investigation and the 2023 BWRX-300 SMR

investigation. Based on the determined age of the shear fracture zone features during Alleghenian shortening, they are not considered an active hazard to the CRN site.

The term “shear-fracture” for these features is a misnomer within the site, as they are not traditional tectonic shear zones. During excavation for the power block area, detailed geologic mapping of the foundations for the SC1 structures shall be performed to provide further characterization of such features, if identified.

2.5.1.2.6.5 Karst Features

Insert the following after the fourth paragraph of ESPA SSAR Section 2.5.1.2.6.5:

Contrary to previous drilling investigations at the CRN Site in which many dissolution features larger than 0.1 ft were described, only two (2) of such cavity size were described in cored rock Clinch River Nuclear Site samples recovered and described in the 2023 CRN Site investigation. One cavity was described in U1-B16 at a depth of 29.4 ft in the rocks of the Witten Formation, while the other cavity was interpreted as a 0.9 ft maximum size based on core loss in U1-B05 between depths of 145.4 and 150.4 ft, within rocks of the Rockdell Formation (Reference 2.5.1-340).

2.5.1.2.6.8 Effects of Human Activities

Renumber Table 2.5.1-18 to Table 2.5.1-18R in the second paragraph of ESPA SSAR Section 2.5.1.2.6.8.

Replace the second sentence of the second paragraph of ESPA SSAR Section 2.5.1.2.6.8 with the following:

Accessing the Water Resources Permits Dataviewer for oil and gas wells reveals four permit applications for Roane County, TN, dating from June 1981 to March 2023, as listed in Table 2.5.1-18R.

Replace Figure 2.5.1-61 with Figure 2.5.1-61R (Sheet 1 of 2) and Figure 2.5.1-61 (Sheet 2 of 2) in the third paragraph of ESPA SSAR Section 2.5.1.2.6.8.

Replace the fourth paragraph of ESPA SSAR Section 2.5.1.2.6.8 with the following:

Construction materials mined or quarried in Tennessee include dimension stone (sandstone and marble), crushed stone, limestone and clay and sand and gravel (Reference 2.5.1-271). Accessing the TDEC Water Resources Permits Mapviewer (Reference 2.5.1-273), Figure 2.5.1-61R (Sheet 1 of 2) (Sheet 1 of 2) and Figure 2.5.1-61 (Sheet 2 of 2) show the water resource permit applications that currently exist within approximately 10 miles of the CRN Site. As shown on this figure several of these water permits are for mining purposes, however, none of these are within 5 mi (8 km) of the CRN Site. The closest quarry to the site is approximately 8 mi (13 km) northwest and is the Roane County Quarry. The quarry produces crushed and broken

limestone. The Dixie Lee quarry is located approximately 8 miles to the east but is currently being reclaimed.

2.5.1.2.6.10 Unforeseen Geologic Conditions

Replace the first sentence of the first paragraph of ESPA SSAR Section 2.5.1.2.6.10 with the following:

Future excavations for SC1 structures would be geologically mapped.

Replace the first sentence of the second paragraph of ESPA SSAR Section 2.5.1.2.6.10 with the following:

Detailed geologic mapping of excavation walls during construction will permit TVA to document the characteristics of dissolution features in the near-surface carbonate rock units and verify whether cavities decrease in size and abundance with depth, as predicted by the 2013 CRN SMR subsurface investigation and geological mapping.

Replace the third paragraph of ESPA SSAR Section 2.5.1.2.6.10 with the following:

The presence of cavities at and below the level of the foundations within the power block area may affect the bearing capacity of the foundation rock mass and groundwater flow. A mitigation plan, including detailed geologic mapping of the excavation floor, a potential grouting program and geophysical surveys to address possible cavities at and below the foundation levels of SC1 structures will be developed based on the excavation method chosen, and executed during construction. The geophysical surveys will be designed to detect cavities below the foundation elevation that could adversely affect foundation performance and are dependent on the excavation method chosen for the BWRX-300 SMR at the CRN Site. Consistent with the ESPA cavity evaluation, two spherical karst features (cavities) were considered to examine the stability of the BWRX-300 RB deeply embedded vertical shaft and surrounding structures using first generation layout of the plant. The details are provided in Subsection 2.5.4. Additional drilling may be required to characterize geophysical anomalies. It is anticipated that the USNRC staff will be notified when the excavation(s) are open for inspection.

2.5.1.2.9 Relational Analysis

Renumber Table 2.5.1-1 to Table 2.5.1-1R in the second paragraph of the General section of EPSA SSAR Section 2.5.1.2.9.

Renumber Table 2.5.1-1 to Table 2.5.1-1R in the first paragraph of the Local Stratigraphy section of EPSA SSAR Section 2.5.1.2.9.

Replace the second paragraph of the Local Stratigraphy subsection of ESPA SSAR Section 2.5.1.2.9 with the following:

As shown on Figure 2.5.1-30R, the BWRX-300 SMR Site power block area has a foundation excavation elevation of approximately 685 ft (209 m) NAVD88. The stratigraphic units that occur

at this elevation in the BWRX-300 SMR Unit 1 power block area include the Benbolt Formation and the Rockdell Formation, with the Fleanor member at depth. Descriptions of these stratigraphic units are also provided in Subsection 2.5.1.2.3.3.

Renumber Figure 2.5.1-30 to Figure 2.5.1-30R in the Local Structural Geology subsection of ESPA SSAR Section 2.5.1.2.9.

Renumber Table 2.5.1-1 to Table 2.5.1-1R in the Local Structural Geology section of EPSA SSAR Section 2.5.1.2.9.

Replace the seventh sentence of the second paragraph of the Local Structural Geology subsection of ESPA SSAR Section 2.5.1.2.9 with the following:

The similarities between the CRBRP Site, the 2013 CRN SMR Site and the 2023 BWRX-300 SMR site are shown on Figures 2.5.1-30R, 2.5.1-37, 2.5.1-80, and 2.5.1-81.

Replace the sixth sentence of the second paragraph of the Dissolution and Karst subsection of ESPA SSAR Section 2.5.1.2.9 with the following:

The Rockdell underlies the northwestern edge of the BWRX-300 Unit 1 power block area, while the Witten Formation crops out south of the power block area and dips to the southeast.

Replace the fifth paragraph of the Dissolution and Karst subsection of ESPA SSAR Section 2.5.1.2.9 with the following:

Figures 2.5.1-30R, 2.5.1-51, and 2.5.1-81 are geologic cross sections drawn parallel to dip. Figure 2.5.1-81 indicates the extent of the CRBRP Site excavation. Figure 2.5.1-30R is based on borings drilled in support of the 2013 CRN SMR and 2023 BWRX-300 SMR subsurface investigations and indicates the extent of the planned Unit 1 power block area. Figure 2.5.1-51 incorporates data from both the CRBRP and the 2013 CRN SMR subsurface investigations. This figure shows the locations of cavities based on the combined project data. Figure 2.5.1-81 shows that the excavation for the CRBRP was planned primarily in the Unit A Upper Siltstone (current Fleanor member) and to a lesser extent in the Unit B Limestone (current lower Rockdell Formation). The stratigraphy and structure of the CRBRP Site is similar to Location B within the 2013 CRN SMR power block area whereas the BWRX-300 SMR Unit 1 location is similar to Location A (Figures 2.5.1-30R and 2.5.1-81). These figures show that the stratigraphic units in the CRBRP excavation and in CRN SMR location B are identical. The differences in stratigraphic nomenclature are discussed above and shown in Table 2.5.1-1R. Except for the Mascot Formation, the karst depression densities and area ratios for the other stratigraphic units within the 2013 CRN SMR power block area are all less than those in the stratigraphic units noted above as occurring to the northwest and southeast of the 2013 CRN SMR power block area.

Replace the second sentence of the first paragraph of the Voids/Cavities Encountered at and Below the Depth of Foundation subsection of ESPA SSAR Section 2.5.1.2.9 with the following:

The CRBRP Site investigation began in 1972, and site drilling was completed in 1980 (References 2.5.1-100 and 2.5.1-303), whereas the 2013 CRN SMR investigation was

conducted in 2013 (Reference 2.5.1-214) and the BWRX-300 SMR subsurface investigation in 2023 (Reference 2.5.1-341).

Replace the Geotechnical Site Investigations subsection of ESPA SSAR Section 2.5.1.2.9 with the following:

The boundary of the 2013 CRN SMR Site investigation and 2023 BWRX-300 SMR subsurface investigations overlaps to a large extent with that of the 1972-1980 CRBRP Site geotechnical site investigation (Figure 2.5.1-74). A total of 104 borings were drilled during the CRBRP Site investigation (Reference 2.5.1-100), 74 were drilled for the 2013 CRN SMR Site investigation (Reference 2.5.1-214) and 27 were drilled for the 2023 BWRX-300 SMR subsurface investigations (Reference 2.5.1-341). All 3 site investigations included widely distributed borings to fully characterize the site stratigraphy and concentrated most borings in the areas of SC1 related facilities. The northern cluster of 2013 CRN SMR Site borings, which corresponds to Location B, is centered northeast of the greatest concentration of borings related to the CRBRP Site investigation and occurs within the same geologic unit (Figure 2.5.1-74). The southern cluster of 2013 CRN SMR Site borings, which corresponds to proposed Location A and the 2023 BWRX-300 SMR Unit 1 location, is centered within the Benbolt formation, a slightly younger geologic unit with similar lithologic characteristics. These three concentrations of borings fall within the Chickamauga Group, a middle Ordovician sequence of limestones, silty and cherty limestones, and calcareous siltstones.

Although the CRBRP utilized a different stratigraphic nomenclature than the 2013 CRN SMR and 2023 BWRX-300 SMR Site boring investigations, the unit designations are directly correlative. The positions of formation contacts correlate well between 2013 CRN SMR, 2023 BWRX-300 SMR and CRBRP borings, which demonstrates consistency in topographic survey and geologic logging. Both programs began rock coring at the top of rock and cored continuously to boring termination.

Cavities encountered in both site investigations were logged to the nearest tenth of a foot, with bottom and top elevations of the cavity recorded. A total of 216 cavities were logged during the CRBRP Site investigation, whereas the 2013 CRN SMR Site investigation logged a total of 23 cavities while the 2023 BWRX-300 SMR site investigation logged only 2 cavities. The fewer number of cavities encountered in the 2013 CRN SMR and 2023 BWRX-300 SMR site borings are consistent with removal of the cavity-rich near-surface strata during the deep CRBRP excavation and associated grading activities prior to 2013 (Figure 2.5.1-74). The CRBRP and 2013 CRN SMR combined cavities dataset is illustrated on the distribution of cavities cross section (Figure 2.5.1-51) and on the plot of cavity size versus elevation (Figure 2.5.1-52). Additionally, the distribution of cavity size vs. elevation of the 2013 CRN SMR Site data is consistent with that of the CRBRP Site data. Based on the quality and compatibility of both boring investigations, the combined dataset was used for CRN Site analysis of cavities in boreholes.

Replace the Conclusions subsection of ESPA SSAR Section 2.5.1.2.9 with the following:

The aforementioned relational analysis provides a comparison of the CRN SMR Site with the CRBRP Site with respect to geologic formation, rock type, geologic structure and occurrence and character of karst and voids/cavities encountered at and below the depth of foundations. The

geologic units mapped in the CRBRP Site excavation (Fleanor member and Rockdell Formation) are the same as those occurring in Location B of the CRN SMR Site power block area. However, interpretation of the subsurface data with respect to the BWRX-300 planned power block reveal that the bulk of the excavation will be within the Benbolt Formation. Except for the Mascot Formation, the karst depression densities and area ratios for the other stratigraphic units within the power block area are all less than those in the stratigraphic units noted above as occurring to the northwest and southeast of the power block area; indicating that the power block area carbonates appear to have similar dissolution characteristics to the Rockdell Formation.

2.5.1.3 References

Replace the following References in ESPA SSAR Section 2.5.1.3:

Notes:

* = Inferred contact in residual soils (Blackford/Five Oaks Formations) MP-421

\+ = Weathered rock depth designation with this marking is based on observation of core and not just sampling method. Therefore, thickness of weathered rock shown may extend below top of rock depths and contain the upper portion of bedrock unit.

(TD) = Total Depth Drilled For Boring

Blank cells indicate formations not encountered for a specific boring.

Horizontal/Vertical Datum: Tennessee State Plane Coordinates (East Zone) NAD83/NAVD88

True unit thickness calculated as follows: Assuming a uniform dip of 33 degrees, true thickness = cos 33 x observed thickness

Depths shown for angle borings are lengths below ground surface measured along the inclination (from vertical) and azimuth of the borings as stated below and are not corrected to represent true vertical depth. Source: Reference 2.5.1-214 and Reference 2.5.1-340

Replace Table 2.5.1-3 with the following:

Table 2.5.1-3R Average Thickness and Variability of Each Stratigraphic Unit

The symbols shown on this map represent water resource permits for various applications such as construction, water treatment plants, individual wells, hydrostatic purposes etc. See the legend to this figure on the next sheet.

Mine locations are shown as ⚒ and include the following on the map:

Roane County Quarry: Crushed and Broken Limestone

Dixie Lee Quarry: Crushed and Broken Limestone; currently being reclaimed by Vulcan Construction

Oak Ridge Quarry: Crushed and Broken Limestone

Clear Energy Corporation (formerly Dalco of Tennessee LLC.): Bituminous Coal and Lignite, Surface

Figure 2.5.1-61R (Sheet 1 of 2) Map Showing the Water Resource Permit Application Sites Within Approximately 10 Miles of the Clinch River Nuclear Site

Renumber Figure 2.5.1-30 to Figure 2.5.1-30R in the Note of Figure 2.5.1-81.

2.5.2 Vibratory Ground Motion

Replace the first paragraph of ESPA SSAR Section 2.5.2 with the following:

This subsection provides a detailed description of vibratory ground motion assessments that were carried out for the Clinch River Nuclear (CRN) Site. Subsection 2.5.2 of the CRN Site ESPA (Reference 2.5.2-196) presented the development of the safe shutdown earthquake (SSE) ground motion response spectra (GMRS) that satisfies the requirements of 10 CFR 100.23, where the GMRS for the power block at the CRN Site was developed by considering a plant parameter envelope (PPE) at Locations A and B (Figure 2.5.4-11). The SSE represents the design earthquake ground motion at the site and is the vibratory ground motion for which certain systems, structures, and components are designed to remain functional. The GMRS is the site-specific ground motion response spectra characterized by horizontal and vertical response spectra determined as free-field motions on the ground surface or as free-field outcrop motions on the uppermost in-situ competent material using performance-based procedures.

In this subsection, the vibratory ground motion is updated to incorporate the requirements for the selected technology and layout at the location of Unit 1 of the CRN Site. Consistent with NEDO-33914-A (Reference 2.5.2-134), three sets of performance-based site-specific response spectra are defined between the foundation level and ground surface elevations, namely, the foundation input, performance-based intermediate and surface response spectra. The foundation input response spectra (FIRS) return the amplitude and frequency content of the design ground motion at the foundation level. The performance-based intermediate response spectra (PBIRS) and surface response spectra (PBSRS) provide the amplitude and frequency content of the design ground motion at the intermediate level and ground surface, respectively. The PBIRS is defined as the outcrop free-field motion at a selected elevation corresponding to significant shear-wave velocity (V_S) contrasts in the subgrade profile. The response spectra were developed with consideration of the guidance provided in SRP 2.5.2, as well as the appropriate sections of Regulatory Guides referenced within that SRP section.

Replace the last sentence of the last paragraph of ESPA SSAR Section 2.5.2 with the following:

Subsection 2.5.2.5.8 describes the development of the horizontal and vertical response spectra (i.e., FIRS, PBIRS, and PBSRS) for Unit 1 at the CRN Site.

2.5.2.1 Seismicity

Replace the last sentence of the third paragraph and the fourth paragraph of ESPA SSAR Section 2.5.2.1 with the following:

For the CRN ESPA, the seismicity catalog was one of the potentially significant data sets requiring an update. While the CEUS SSC Report was published in 2012, its seismicity characterization was based on data only through the end of 2008, therefore, a review of more recent seismicity was warranted and was undertaken as part of the CRN ESPA.

To evaluate the potential significance of any re-interpretation of past earthquakes and to consider the impact of more recent seismicity, the CEUS SSC earthquake catalog was reviewed and updated for the CEUS for the time period from the beginning of 2009 through mid-September 2013 as part of the CRN ESPA. Further review and update of the CEUS SSC earthquake catalog was performed as part of a PSHA for the Y-12 National Security Complex in Oak Ridge, Tennessee (Reference 2.5.2-150) for the time period through 2018. The catalog for the Y-12 PSHA also included catalog revisions documented in EPRI Technical Report 3002005288 (Reference 2.5.2-212).

2.5.2.1.1 Regional Earthquake Catalog Developed for the CEUS SSC Study

Renumber Figure 2.5.2-17 to Figure 2.5.2-17R in EPSA SSAR Section 2.5.2.1.1.

2.5.2.1.2 Updated CEUS SSC Earthquake Catalog

Renumber Table 2.5.2-2 to Table 2.5.2-2R in EPSA SSAR Section 2.5.2.1.2.

Insert the following after the last paragraph of ESPA SSAR Section 2.5.2.1.2:

For the Y-12 PSHA, the CEUS earthquake catalog was updated using the CEUS SSC methodology and including events through 2018. The updated catalog for the Y-12 PSHA also includes catalog revisions documented in EPRI Technical Report 3002005288.

2.5.2.1.3 Induced Earthquakes

Replace the second sentence of the first paragraph of ESPA SSAR Section 2.5.2.1.3 with the following:

Since about 2009 there has been a notable increase in the number of small to moderate magnitude earthquakes in several regions of the CEUS, including parts of Arkansas, Oklahoma, Kansas, and Texas, largely attributed to human activities involving subsurface fluid injection—including one in November 2011 with a magnitude of 5.6 (Petersen and others, 2015) (Reference 2.5.2-5) and one in September 2016 with a magnitude of 5.8 (Reference 2.5.2-213).

Insert the following after the last paragraph of ESPA SSAR Section 2.5.2.1.3:

The updated earthquake catalog for the Y-12 PSHA includes catalog revisions documented in EPRI Technical Report 3002005288. The EPRI Technical Report 3002005288 earthquake catalog includes updates for reservoir-induced seismicity in the southeastern United States and for some earthquakes related to the large Charleston, South Carolina earthquake in 1886.

2.5.2.1.4 Significant Site Region Earthquakes

Replace the first paragraph of ESPA SSAR Section 2.5.2.1.4:

This subsection presents available information on the three cataloged earthquakes of E[**M**] 5.0 or greater occurring within 320 km (200 mi) from the CRN Site.

Insert the following after the last paragraph of ESPA SSAR Section 2.5.2.1.4:

August 9, 2020 MW 5.1

Sparta, North Carolina

Distance to CRN Site = 302 km (188 mi)

The August 9, 2020, **M** 5.1 Sparta earthquake located ~ 3 km (~ 2 mi) south of Sparta, North Carolina (Reference 2.5.3-82), approximately 302 km (188 mi) ENE of the CRN site. The Sparta earthquake was the largest in North Carolina in nearly 100 years and the strongest in the eastern United States since the 2011 **M** 5.8 (E[**M**] 5.71) Mineral, Virginia earthquake. The earthquake sequence included eight foreshocks (**M** 1.8-2.6) during the previous 24 hours before the mainshock and at least 300 aftershocks over the next six months (up to MW 2.9) (Reference 2.5.3-82). The mainshock had a maximum intensity of VI-VII in Sparta and generated peak ground accelerations of at least 0.2 g. According to the USGS (Reference 2.5.3-86) an intensity of II was recorded at the CRN site area.

The mainshock hypocenter and focal mechanism have been estimated independently by several groups (Figure 2.5.3-23), namely the Center for Earthquake Research and Information at the University of Memphis (CERI) (Reference 2.5.3-87), the Saint Louis University Earthquake Center (Reference 2.5.3-88) and the United States Geological Survey (Reference 2.5.3-86). While the first two entities calculated the depth of the hypocenter at 0.6 mi (1 km) or less, the USGS hypocenter is now established to be 2.5 mi (4.1 km) (Reference 2.5.3-86) and is the preferred location (Reference 2.5.3-82). Although all three calculations resulted in a NW-SE to WNW-ESE striking plane with dips between approximately 50-60° SW for the focal mechanism, the preferred USGS (Reference 2.5.3-86) orientation is 176, 48° W for the nodal plane (Reference 2.5.3-82). These orientations are all oblique to the regional NE-SW structural trend.

The Sparta earthquake produced the first documented seismic surface rupture in the eastern United States allowing identification of the Little River Fault (Reference 2.5.3-82). Although the Little River Fault produced strong ground shaking and surface rupture, the geomorphology and focal mechanism analysis of fault seismicity is suggestive of an underlying structural control (Reference 2.5.2-223; Reference 2.5.2-225) and evidence for repeated fault movements within the Quaternary have been documented (Reference 2.5.2-224; Reference 2.5.2-225), it is not considered a hazard to the CRN Site. This is primarily because the Little River Fault only has ~2.5 mi (4 km) of documented surface rupture, which is less than the 4.3 mi (7 km) length criteria needed to be considered a seismic hazard by the U.S. Geological Survey National Seismic Hazard Model (NSHM) for the conterminous United States. For this reason, the Little River Fault

is not included as a fault section in the updated 2023 National Seismic Hazard Model database (Reference 2.5.2-223).

Furthermore, the Sparta earthquake is not within the ETSZ (Figure 2.5.2-222) and is not considered related to the same tectonics as the ETSZ, as it was a shallow event (~0.6 mi (1 km) depth) and all events in the ETSZ have deep sources (4.3-15.5 mi (7-25 km) depth) (Reference 2.5.2-226). The Sparta earthquake and Little River Fault are discussed in more detail in Subsection 2.5.3.7.1.

The Sparta earthquake occurred within the Site Region and caused surface rupture along the Little River Fault (Reference 2.5.3-82), indicating that it is likely a capable tectonic source. The Little River Fault is however outside of the ETSZ, and the Sparta earthquake was determined to be shallow (<3 mi (5 km)) (Reference 2.5.3-87) indicating that it does not fit into the characteristics of the ETSZ. The Little River Fault is therefore not considered a ground motion or faulting hazard to the CRN Site. Future earthquakes associated with it are adequately represented by the CEUS SSC distributed seismicity source zones in which it is located.

2.5.2.2 Geologic and Tectonic Characteristics of the Site and Region

2.5.2.2.1 Overview of CEUS SSC

2.5.2.2.5 Post-CEUS SSC Studies

Insert the following after the last paragraph of ESPA SSAR Section 2.5.2.2.5:

Subsequent SSHAC Level 2 studies performed for other sites in the region (i.e., Savannah River Site (SRS), the Y-12 National Security Complex (Y-12), and Oak Ridge National Laboratory (ORNL)) indicate the need to update other elements of the CEUS-SSC model for use at the CRN Site. These updates are needed for the New Madrid Seismic Zone (Subsection 2.5.2.2.5.3) and the Charleston Seismic Zone (Subsection 2.5.2.2.5.4). Evaluations of new data and investigations from the Eastern Tennessee Seismic Zone (ETSZ) indicate that no changes to the CEUS-SSC model are required for the characterization of the ETSZ (Subsection 2.5.2.2.5.1).

Also, as mentioned in Sections 2.5.2.1.2 and 2.5.2.1.3, for the Y-12 PSHA, the earthquake catalog was updated using the CEUS SSC methodology to include events through 2018. The

update also included revisions related reservoir-induced and Charleston-era earthquakes as documented in Reference 2.5.2-212.

Rename and Replace ESPA SSAR Section 2.5.2.2.5.1 with the following:

2.5.2.2.5.1 Investigations of the Eastern Tennessee Seismic Zone

The ETSZ is an approximately 300- to 400-km-long and 50-km-wide, northeasterly trending, elongate band of seismicity in the Valley and Ridge and western Blue Ridge physiographic provinces (Reference 2.5.2-128; Reference 2.5.2-173) (Figure 2.5.2-26). The ETSZ underlies eastern Tennessee, and parts of North Carolina, Georgia, and Alabama (e.g., Reference 2.5.2-130; Reference 2.5.2-133; Reference 2.5.2-128; Reference 2.5.2-90). After the New Madrid seismic zone, the ETSZ has the second highest rate of small (**M** < 5) earthquakes in the eastern U.S. but what localizes modern strain release in eastern Tennessee is still an open question (Reference 2.5.2-135; Reference 2.5.2-141).

In the CEUS-SSC model, the ETSZ was not modeled as a distinct seismic source, due to the lack of evidence for repeated, large-magnitude earthquakes or other distinguishing characteristics. Instead, the CEUS-SSC model uses the spatial smoothing of seismicity to maintain the locally high seismicity rates in the ETSZ, and assigns a broad distribution on magnitude, including very large-magnitude earthquakes, for those distributed seismicity sources that host the ETSZ. Thus, the CEUS-SSC model allows for relatively frequent and large-magnitude earthquakes in the eastern Tennessee region.

Studies of the ETSZ that post-date development of the CEUS-SSC model have examined the deep crustal structure (Reference 2.5.2-148; Reference 2.5.2-149; Reference 2.5.2-155) and the shallow crustal structure (Reference 2.5.2-158 Reference 2.5.2-157). Reference 2.5.2-159) suggest that the 2012 **M** 4.2 Perry County, Kentucky, earthquake is related to the ETSZ, thus extending the zone farther north than previously recognized. Yang and Salem (2016) (Reference 2.5.2-160) used Permanent Scatterers Synthetic Aperture Radar Interferometry (PSInSAR) data to suggest that land surface deformation may be spatially associated with areas of higher seismicity rate in eastern Tennessee, but caution that many other processes besides earthquake activity can contribute to surface deformation. Gallen and Thigpen (Reference 2.5.2-162) present a model in which lithological focusing of transient erosion in the Upper Tennessee drainage basin has augmented the local stress field through redistribution of surface loads, allowing preexisting basement structures to slip in the regional stress field.

Several paleoseismic studies in the ETSZ post-date the CEUS-SSC. Hatcher et al. (Reference 2.5.2-88) interpreted potential paleoseismic features near Douglas Reservoir as evidence for at least two **M** ≥ 6.5 earthquakes in the ETSZ in the last approximately 73-112 ka. Related and other studies are published as a Geological Society of America (GSA) field trip guidebook (Reference 2.5.2-163), student theses (e.g., Reference 2.5.2-89; Reference 2.5.2-168), numerous abstracts (e.g., Reference 2.5.2-214; Reference 2.5.2-215; Reference 2.5.2-216; Reference 2.5.2-217; Reference 2.5.2-172), and elsewhere.

A recent paper by Cox et al. (Reference 2.5.2-173) summarizes and synthesizes the relevant paleoseismic and geomorphic information, so much of the discussion that follows relies on this recent synthesis paper. Building on previous studies, Cox et al. (Reference 2.5.2-173) proposed an approximately 80- to 110-km-long, northeast-trending zone of active faulting in the ETSZ that extends from approximately the Douglas Reservoir near Dandridge, Tennessee on the northeast to at least Vonore, Tennessee on the southwest. They named this the Dandridge-Vonore fault corridor. Along this trend they interpret Quaternary-active reverse, strike-slip, and normal faults from trench excavations and natural exposures. At the Dandridge site, a thrust fault exposed in French Broad River alluvium previously identified by Hatcher et al. (Reference 2.5.2-88) and Warrell et al. (Reference 2.5.2-217) is interpreted as recording two earthquakes in the last 40 ka. Approximately 50 km southwest near Alcoa, Tennessee, Cox et al. (Reference 2.5.2-173) interpret evidence for two earthquakes between 15 and 10 ka from a riverbank exposure of a thrust fault that cuts Little River alluvium. Approximately 30 km farther southwest near Vonore, Tennessee, they interpret thrust and normal faults on the north and south sides of the Little Tennessee River valley. They interpret the thrust fault displaces Quaternary alluvium ≥ 2 m over bedrock, and the alluvium is normal faulted > 2 m. Based on these observations, Cox et al. (Reference 2.5.2-173) interpret at least two **M** ≥ 6.5 earthquakes in the Dandridge-Vonore fault corridor in the last 40 ka. If this interpretation is correct, it would suggest the need for an RLME source to model future earthquakes in the Dandridge-Vonore fault corridor.

A recent paper by USGS and USNRC geologists documents their evaluation of evidence for and against tectonic surface deformation in the ETSZ (Reference 2.5.2-174). They conclude that evidence for tectonic surface deformation remains elusive in the ETSZ. Thompson Jobe et al. (Reference 2.5.2-174) visited Cox et al.'s (Reference 2.5.2-173) Alcoa paleoseismic site on the Little River, where Cox et al. (Reference 2.5.2-173) interpreted two late Pleistocene earthquakes based on fault relationships exposed along the riverbank. Thompson Jobe et al.'s (Reference 2.5.2-174) preferred interpretation of this same site is that it records a series of cut and fill channels with some mass wasting and bank-collapse features that were deposited on top of a bedrock strath surface. In other words, Thompson Jobe et al. (Reference 2.5.2-174) interpret that the exposure is likely the result of fluvial processes, as opposed to young faulting.

The results of the ongoing paleoseismic studies in the ETSZ are preliminary and do not provide adequate evidence for defining the ages and repeat times of earthquakes and therefore do not provide adequate evidence for defining an RLME seismic source for the ETSZ. This conclusion is consistent with the 2023 version of the National Seismic Hazard Model (NSHM23; (Reference 2.5.2-175; Reference 2.5.2-176), which also excludes the ETSZ as a discrete seismic source. Additional rationale for excluding the ETSZ as a source in the SSC for the CRN Site is provided by hazard sensitivity tests, as described in Subsection 2.5.2.2.6.1.3.

2.5.2.2.5.2 Investigations of the 2011 Mineral, Virginia Earthquake

Insert the following after the last paragraph of ESPA SSAR Section 2.5.2.2.5.2:

Also, the potential source does not exhibit evidence of two or more earthquakes with **M** ≥ 6.5.

Add new Section 2.5.2.2.5.3:

2.5.2.2.5.3 Investigations of the New Madrid Seismic Zone

The New Madrid Seismic Zone (NMSZ) is an area of elevated seismicity rate in the northern Mississippi embayment in parts of Missouri, Arkansas, Tennessee, Mississippi, and Illinois. The New Madrid Fault System (NMFS) is the source of the 1811–1812 New Madrid earthquake sequence, which includes three of the largest earthquakes to have occurred within the North American plate in historical times (Reference 2.5.2-178).

In the CEUS-SSC model, the NMSZ is modeled by five RLME sources: the New Madrid Fault System (NMFS), Eastern Rift Margin-North (ERM-N), Eastern Rift Margin-South (ERM-S), Marianna, and Commerce Fault Zone (Commerce) sources (Figure 2.5.2-22R). The magnitudes and rates for these RLMEs are based in part on paleoseismic and paleoliquefaction records. In the CEUS-SSC, the NMFS RLME is modeled by fault sources, the ERM-N, ERM-S, and Commerce RLMEs are modeled as narrow, elongated “fault-like” source zones, and the Marianna RLME is modeled as a roughly square-shaped source zone.

Since publication of the CEUS-SSC model in 2012, several studies provide relevant new information on the NMSZ seismic sources, and this information was used to update the NMSZ RLME sources for the CRN Site. Much of that new information is summarized in the documentation of the NSHM23 (Reference 2.5.2-223; Reference 2.5.2-175; Reference 2.5.2-176). Subsection 2.5.2.2.5.3.1 summarizes new information on the NMFS RLME. Subsection 2.5.2.2.5.3.2 summarizes new information on the other four RLMEs in the NMSZ (ERM-N, ERM-S, Commerce, and Marianna). Subsection 2.5.2.2.5.3.3 summarizes changes to the NMSZ RLMEs based on this new information.

2.5.2.2.5.3.1 New Information on the New Madrid Fault System (NMFS) RLME

This subsection describes new data that post-date the CEUS-SSC for the NMFS RLME, and is organized into discussions of source geometry, magnitude, and recurrence.

Geometry: In the CEUS-SSC, the fault sources that compose the NMFS RLME include the New Madrid South fault, the New Madrid North fault, and the Reelfoot thrust (Figure 2.5.2-22R). Uncertainties in the locations, extents, and rupture combinations of these faults are included in a complex logic tree in the CEUS-SSC for the New Madrid Fault System RLME (Figure 2.5.2-22R).

For the NMFS, the NSHM23 model updates the names of some and geometries of all the constituent faults, as shown in Figure 2.5.2-24R. For example, the Blytheville Arch (BA) fault name is changed to the Axial Fault (AF), and it is extended approximately 35 km farther southwest based on seismic reflection data in Reference 2.5.2-179. Similarly, the short and long depictions of the Reelfoot Thrust fault source (RFT-S and RFT-L, respectively) are renamed the New Madrid West (NMW) and Reelfoot faults, with minor changes to their geometries. These new names and, with one exception, geometries are adopted for use in this project. Consistent with NSHM23, the southeastern extent of the Reelfoot fault has been moved to the southwest to align with new observations of deformed late Pleistocene terraces (Reference 2.5.2-180). One

additional change was made to the to the geometry of the Reelfoot fault source for use at the CRN Site. In the NSHM23 model, the NMW and Reelfoot faults are discontinuous and do not connect with one another. The USGS PSHA software allows fault ruptures to “jump” across fault discontinuities, but the PSHA software used for this project does not. For this reason, the northwest end of the Reelfoot fault source was modified so that it directly connects with the NMW source to allow for combined ruptures on these two faults (Figure 2.5.2-24R). Given the distance to the CRN Site, this minor change in source geometry for the Reelfoot fault is assumed to be insignificant to hazard.

Magnitude: In the CEUS-SSC model, the NMFS RLME is characterized with a broad Mmax distribution that ranges from **M** 6.7–7.9 (Table 2.5.2-11). Since publication of the CEUS-SSC model, several studies provide new information on earthquake magnitudes for the NMFS. For example, Boyd and Cramer (Reference 2.5.2-182) derived a new macroseismic intensity prediction equation for the central and eastern U.S. to estimate magnitudes of the 1811–1812 New Madrid earthquakes. Their mean estimate ranges are near the lower range of estimates from previous studies and include **M** 6.9–7.1 for the 16 December 1811 earthquake, **M** 6.8–7.1 for the 23 January 1812 earthquake, and **M** 7.3–7.6 for the 7 February 1812 earthquake. Boyd and Cramer (Reference 2.5.2-182) caution that there is significant uncertainty associated with these estimates, and that one-sigma uncertainties could be as large as 0.3-0.4 magnitude units.

Cramer and Boyd (Reference 2.5.2-183) evaluated intensity data at large distances to estimate magnitudes for the historical New Madrid earthquakes that are slightly greater than the estimates from Boyd and Cramer (Reference 2.5.2-182). Cramer and Boyd’s (Reference 2.5.2-183) magnitude estimates for the three 1811-1812 mainshocks are: **M** 7.5 for the 16 December 1811 earthquake, **M** 7.3 for the 23 January 1812 earthquake, and **M** 7.7 for the 7 February 1812 earthquake. For each event, Cramer and Boyd (Reference 2.5.2-183) estimate an uncertainty of 0.3 magnitude units at the 95% confidence level.

Chung and Rogers (Reference 2.5.2-184) reevaluated intensity data from southeast Missouri to calculate a best-estimate magnitude for the 7 February 1812 earthquake of **M** 7.7. This estimate is the same as that from Cramer and Boyd (Reference 2.5.2-183) for the same event.

Ramirez-Guzman et al. (Reference 2.5.2-185) performed a suite of numerical simulations based on the 1811–1812 earthquakes, and these simulations included 3-D geologic structures and rupture directivity effects out to distances of about 500 km. They conclude that basin response and rupture directivity effects have significant impacts on patterns and levels of estimated intensities, which lead to additional uncertainty not previously considered in magnitude estimates for the 1811–1812 earthquake sequence based only on historical reports. As such, the Ramirez-Guzman et al. (Reference 2.5.2-185) study suggests that a broad range in magnitude, such as is currently used in the CEUS-SSC model, is appropriate for the NMFS RLME.

The magnitude distributions for the NMFS from the CEUS-SSC (**M** 6.7–7.9) and the NSHM23 (**M** 6.8–8.0) are in close agreement, with the weighted mean magnitude from the CEUS-SSC slightly higher.

The new magnitude data described above fall within the range of values currently included in the CEUS-SSC model for the NMFS RLME. Thus, no revisions to the CEUS-SSC are required to account for these new magnitude data.

Recurrence: Several new studies provide recurrence information for the NMFS. For example, Page and Hough (Reference 2.5.2-186) examined historical and instrumental seismicity in the New Madrid region to determine whether present-day activity is predominantly aftershocks of the 1811–1812 sequence. They conclude that the ongoing seismic activity is not entirely explained as aftershocks and that distributed (background) seismicity is driven by ongoing strain accumulation, albeit at low rates.

Craig and Calais (Reference 2.5.2-187) evaluated approximately 15 years of continuous GPS data in the New Madrid region to conclude that motions are consistently within the 95% confidence limit of zero deformation. Their data place an upper bound on strain accrual of 0.2 mm/yr for faults in the New Madrid seismic zone. Craig and Calais (Reference 2.5.2-187) argue that the low strain accrual rate is inconsistent with the 500–900-year repeat time of paleoearthquakes in mid- to late Holocene time, and that their results are consistent with temporal clustering of earthquake behavior on the New Madrid fault system.

Boyd et al. (Reference 2.5.2-188) modeled Global Navigation Satellite System (GNSS) data from 2000–2014 across the New Madrid region to evaluate between several deformation mechanisms. They indicate that many of the recent earthquakes appear to be part of a long-lived aftershock sequence related to the 1811–1812 earthquakes, and that present strain accrual rates are very low to zero. However, they caution that their results are consistent with temporal clustering of large earthquakes and that seismic hazard likely remains significant.

New paleoseismic event ages in the NMFS are provided in recent studies by Tuttle et al. (Reference 2.5.2-220) and Gold et al. (Reference 2.5.2-189). Tuttle et al. (Reference 2.5.2-220) suggest a newly recognized liquefaction event at approximately A.D. 0 and revised timing of an 1811–1812-like compound event at approximately 1050 B.C. In the CEUS-SSC model for the NMFS “All In” branch, earthquake recurrence is computed based on the most-recent three events only (i.e., A.D. 1811–1812, 1450, and 900) because the older portion of the paleoliquefaction record was judged to be incomplete. For the CRN PSHA, it was concluded that the older portion of the record remains incomplete, the results of Tuttle et al. (Reference 2.5.2-220) notwithstanding. In another recent study, Gold et al. (Reference 2.5.2-189) provide event ages for sackungen features in the NMSZ and they observe that the timing of these sackungen-forming events corresponds to previously documented earthquakes in the region.

As such, based on evaluations of new studies by Tuttle et al. (Reference 2.5.2-220), Gold et al. (Reference 2.5.2-189), and others, no changes were made to the recurrence data of large-magnitude earthquakes in the NMFS RLME, which was based on the record of the three most-recent clusters of events that comprise the “complete” portion of the paleoseismic record.

The CEUS-SSC includes two alternative models for large-earthquake recurrence of the NMFS RLME source: (1) the Poisson (time independent) model; and (2) the Brownian Passage Time or “renewal” (time-dependent) model. The Poisson model assumes that the average time between

events is known, but the exact timing of events is independent of the time since the last and previous events. A renewal model for the occurrence probability of earthquakes is appropriate when the data suggest a more periodic recurrence behavior than is implied by the Poisson model. Renewal models typically are used where a fault is subjected to quasi steady-state loading, such as may occur in a plate boundary setting. In the CEUS-SSC, much greater weight was given to the Poisson model (0.75 weight) than the renewal model (0.25 weight) when on the "All In" branch for the NMFS (Figure 2.5.2-25R).

Faults in the NMFS RLME are reasonably well understood, and the recurrence of large-magnitude earthquakes appears quasi-periodic, at least when in a cluster. The strain loading mechanism for the NMFS remains unclear, but the strain release rates over the last several earthquake cycles are comparable to some plate boundary settings. For these reasons, the CEUS-SSC model weights were revised to give equal weights to the Poisson and renewal models of earthquake recurrence for the NMFS when on the "All In" branch of the NMFS logic tree. Given the apparent quasi-periodic behavior of the NMFS over the last few earthquake cycles and the relatively fast loading rate implied by the high rate of earthquake occurrence, this increased weight to the renewal model is justified.

2.5.2.2.5.3.2 New Information on the ERM-N, ERM-S, Commerce, and Marianna RLMEs

This subsection summarizes new information that post-dates CEUS-SSC on the ERM-N, ERM-S, Commerce, and Marianna RLME sources.

ERM-N and ERM-S: In the CEUS-SSC, the ERM-N and ERM-S RLME sources are modeled as narrow, elongated "fault-like" source zones. These northeast-trending zones are "leaky" at both ends such that ruptures that nucleate within the zones are allowed to extend partially outside the zones. In the NSHM23, the USGS has collapsed these polygonal source zones into fault sources with single traces, given the relatively good definition of the fault at the surface and at depth (Figure 2.5.2-24R) (Reference 2.5.2-223; Reference 2.5.2-176). In the NSHM23, the southern extent of the ERM-N source is extended 12 km to the south. Magnitudes and rates for the ERM-N and ERM-S sources are based on historical and paleoliquefaction records, as opposed to fault dimensions, so no changes are needed for magnitudes and rates. In the CEUS-SSC, the names of the alternative southern extensions of ERM-S are Crittenden County (CC) and RP (River Picks); in the NSHM23, the RP name is changed to Meeman-Shelby (MS). These changes to geometry and names are adopted for the CRN Site.

Commerce: In the CEUS-SSC, the Commerce RLME source is modeled as a narrow, elongated "fault-like" source zone. This northeast-trending zone is "leaky" at both ends such that ruptures that nucleate within the zone are allowed to extend partially outside the zone. In the NSHM23, the USGS has collapsed this polygonal source zone to a fault source with a single 75-km-long trace (Figure 2.5.2-24R), given the relatively good definition of the fault at the surface and at depth (Reference 2.5.2-223; Reference 2.5.2-176). This change to geometry is adopted for the CRN Site.

Marianna: The Marianna RLME source is based mainly on paleoliquefaction evidence for repeated, large-magnitude earthquakes. In the Marianna region, Odum et al. (Reference 2.5.2-195) collected new seismic reflection data across the Daytona Beach

lineament, a northwest-trending, >10-km-long tonal lineament seen in aerial photographs. From these data they interpret a fault zone that offsets Tertiary and possibly Quaternary units. Tuttle et al. (Reference 2.5.2-197) document the identification and dating of large sand blows along the Daytona Beach lineament, including three Holocene events and at least two late Pleistocene events. Tuttle et al. (Reference 2.5.2-197) speculate that the paleoliquefaction may have formed by large earthquakes on the fault that underlies the Daytona Beach lineament.

In their documentation of earthquake geology inputs for the NSHM23, Thompson Jobe et al. (Reference 2.5.2-223) conclude that it is unclear whether the Daytona Beach lineament produced any of the documented paleoliquefaction and that considerable uncertainty remains regarding the locations, extents, and activities of other potentially active faults in the Marianna RLME source zone (Figure 2.5.2-24R). For these reasons, no updates were made to the NSHM23 characterization of the Marianna source (Reference 2.5.2-176). The new data from the Marianna area are interesting, but currently no changes to the CEUS-SSC model of the Marianna RLME source are required for the CRN Site.

2.5.2.2.5.3.3 Summary of Changes to CEUS-SSC

This section describes changes to the CEUS-SSC models for the five RLME sources in the NMSZ that are documented in Reference 2.5.2-265.

NMFS RLME: Two changes have been implemented. The first is to adopt the changes to fault source names and geometries based on the NSHM23, as shown in Figure 2.5.2-24R. The second is to assign equal weight to the Poisson and renewal models of time dependence for the “All In” branch of the NMFS RLME.

ERM-N, ERM-S, and Commerce RLMEs: In the NSHM23, the geometries of the ERM-N, ERM-S, and Commerce RLME sources are changed from narrow, elongated source zones to fault sources (Figure 2.5.2-28R). For use at the CRN Site, the revised fault source geometries are adopted from NSHM23 for the ERM-N, ERM-S, and Commerce RLME sources. Besides their geometries, no other changes are made to these three RLME sources.

Marianna RLME: In the NSHM23, there are no changes to the CEUS-SSC characterization of the Marianna RLME. We are not aware of any significant new data for the Marianna RLME. As such, the Marianna RLME source is adopted as-is from the CEUS-SSC for use at the CRN Site.

Add new Section 2.5.2.2.5.4:

2.5.2.2.5.4 Investigations of the Charleston Seismic Zone

The Charleston seismic zone is an area of elevated seismicity rate near Charleston, South Carolina. The CEUS-SSC characterization of the Charleston RLME source was recently updated as part of an augmented SSHAC Level 2 study performed for the Savannah River Site (SRS) by Lettis Consultants International, Inc. (Reference 2.5.2-198). This subsection summarizes the changes, and the rationale for those changes, to the Charleston RLME that were used at the SRS and are adopted for use at the CRN Site. The SRS augmented SSHAC Level 2 report

---

provides more complete documentation (Reference 2.5.2-198). Data that post-date the SRS augmented SSHAC Level 2 study are summarized in Subsection 2.5.2.2.5.4.1.

Magnitude: In the CEUS-SSC model, the magnitude distribution for future Charleston earthquakes is based on magnitude estimates for the 1886 and prehistoric Charleston earthquakes. This distribution ranges from **M** 6.7–7.5, with a weighted mean of **M** 7.1 (Table 2.5.2-10). Since publication of the CEUS-SSC, several studies have provided additional information on magnitudes of the 1886 and prehistoric 1886-type Charleston earthquakes. For example, Boyd and Cramer (Reference 2.5.2-182) derived a new macroseismic intensity prediction equation for the CEUS to estimate a magnitude of **M** 6.9 ± 0.3 for the 1886 earthquake. Similarly, Cramer and Boyd (Reference 2.5.2-183) estimated a magnitude of **M** 7.0 ± 0.3 for the 1886 event.

Gheibi and Gassman (Reference 2.5.2-199) analyzed geotechnical data from the Hollywood, South Carolina paleoliquefaction site to estimate a minimum earthquake magnitude range of **M** 5.6–6.5 for prehistoric earthquakes that triggered sand blows in the Charleston seismic source zone. More recently, Gheibi et al. (Reference 2.5.2-200) analyzed geotechnical data from several paleoliquefaction sites in the Charleston area to estimate minimum earthquake magnitudes. Based on data from the Hollywood, Sampit, and Gapway sites, Gheibi et al. (Reference 2.5.2-200) estimated a minimum earthquake magnitude range of **M** 5.5–7.2 for prehistoric earthquakes in the Charleston seismic source zone. Based on data from the Fort Dorchester site, Gheibi et al. (Reference 2.5.2-201) estimated a minimum earthquake magnitude range of **M** 5.0–6.3, and Gheibi et al. (Reference 2.5.2-200) estimated a minimum earthquake magnitude range of **M** 5.1–5.7.

Taken together, the new data on the magnitude of the 1886 earthquake and on the minimum magnitudes of liquefaction-inducing prehistoric earthquakes are consistent with the magnitude distribution defined in the CEUS-SSC for the Charleston RLME source. As such, no revisions to the CEUS-SSC are required to account for the new magnitude information.

Fault Geometry and Style: The CEUS-SSC defines three alternative geometries for the Charleston RLME source, based on the distribution of paleoliquefaction features, instrumental seismicity, and subsurface faults interpreted from seismic reflection and other data (Figure 2.5.2-22R). The “Local” source alternative was designed to include the 1886 meizoseismal area, concentrated microseismicity in the Middleton Place-Summerville seismic zone, the preponderance of 1886 liquefaction features, and numerous postulated faults. In the CEUS-SSC model, the Local source alternative is characterized by:

- A relatively high weight of 0.5
- Future earthquake ruptures that are oriented northeast, parallel to the long axis of the zone and the regional structural grain of the Appalachian orogen
- Future ruptures that are modeled as occurring on vertical strike-slip faults
- All boundaries of the Charleston Local source are strict, such that ruptures are not allowed to extend beyond the zone boundaries

The “Narrow” source alternative was defined to contain postulated north-northeast-striking structures such as the Woodstock fault, the southern segment of the East Coast fault system, and Chapman and Beale’s (Reference 2.5.2-83) “fault C.” In the CEUS-SSC model, the Narrow source alternative is characterized by:

- A moderate weight of 0.3
- Future earthquake ruptures that are oriented north-northeast, parallel to the long axis of the zone
- Future ruptures that are modeled as occurring on vertical strike-slip faults
- The northeast and southwest boundaries of the Narrow source are leaky, such that ruptures that initiate within the zone are allowed to extend beyond the zone boundaries in those directions, but by no more than 50% of the rupture length beyond the boundary. The northwest and southeast boundaries of the Charleston Narrow source are strict, such that ruptures are not allowed to extend beyond the zone boundaries to the northwest and southeast.

The “Regional” source alternative is a relatively large area that envelops both the Local and Narrow alternatives, covers most of coastal South Carolina, and extends offshore to include the Helena Banks fault zone. In the CEUS-SSC model, the Regional source alternative is characterized by:

- A relatively low weight of 0.2
- Future ruptures that are oriented either: (1) parallel to the long axis of the source (northeast) with 0.8 weight; or (2) parallel to the short axis of the source (northwest) with 0.2 weight
- Future ruptures that are modeled as occurring on vertical strike-slip faults
- All boundaries of the Charleston Regional source are strict, such that ruptures are not allowed to extend beyond the zone boundaries

Several studies that post-date the CEUS-SSC model provide new information on possible fault locations, geometries, and styles for the Charleston RLME source. Pratt et al. (Reference 2.5.2-202) interpreted reprocessed seismic reflection data in the epicentral area of the 1886 earthquake and identified generally steeply dipping faults that cut Cretaceous- and Cenozoic-age Coastal Plain strata. Pratt et al. (Reference 2.5.2-202) describe two main faults in the Charleston epicentral area, both of which are interpreted as striking northeast. The first was previously identified by Chapman and Beale (Reference 2.5.2-83) and was incorporated into development of the CEUS-SSC model. The second is located approximately 15 km northwest of Charleston where it crosses the Ashley River. Based on the steep fault dips and lack of detectable surface scarps for the 1886 event, Pratt et al. (Reference 2.5.2-202) suggest a component of strike-slip for faulting but acknowledge that some modern focal mechanisms indicate thrust motion. Pratt et al.’s (Reference 2.5.2-202) northeast-striking, steeply dipping faults are consistent with the characterization of the location, strike, and dip of the Local and Narrow source zones.

Hardy (Reference 2.5.2-203) and Chapman et al. (Reference 2.5.2-204) describe data collected during the period 2011 to 2012 from an eight-station seismic network located in the Charleston

epicentral area. The network located 134 earthquakes with duration magnitudes ranging from MD -1.8 to 2.6, and they observed that the earthquakes occurred in a tabular zone striking approximately N186°E and dipping approximately 43°W. From these data, Chapman et al. (Reference 2.5.2-204) interpret that the modern microseismicity is the lingering aftershock sequence of the 1886 earthquake, and that hypocentral locations and focal mechanisms suggest the 1886 earthquake was produced by reverse slip on a south-striking, moderately west-dipping fault plane. Chapman et al.'s (Reference 2.5.2-204) postulated source of the 1886 earthquake is in the Narrow seismic source, although they suggest the 1886 Charleston seismic source may be a west-dipping reverse fault, as opposed to vertical strike-slip as modeled in the CEUS-SSC.

Liberty (Reference 2.5.2-205) describes ongoing work to identify and characterize active faults in the 1886 epicentral area from seismic reflection data. He identifies evidence for a 4-km-wide zone of faulting and folding in the 1886 epicentral area, evidence for possible Quaternary slip on Talwani and Durá-Gómez's (Reference 2.5.2-206) Woodstock fault, and faults consistent with a northeast-striking zone of deformation identified by Chapman and Beale (Reference 2.5.2-83). The (Reference 2.5.2-206) and Chapman and Beale (Reference 2.5.2-83) studies were available during development of, and were incorporated into, the CEUS-SSC.

In a presentation for the Charleston Area Earthquake Hazard Mapping Project (CAEHMP), Cramer (Reference 2.5.2-207) describes ongoing work to develop seismic and liquefaction hazard maps for the Charleston area based on three alternative sources for the 1886 earthquake. These alternative sources are Talwani and Dur-Gómez's (Reference 2.5.2-206) Woodstock fault, Chapman et al.'s (Reference 2.5.2-204) west-dipping fault, and a simple vertical strike-slip fault in the Summerville area. Scenario **M** 7.0 PGA hazard maps from these alternative sources were compared with building and chimney destruction locations documented by Bollinger (Reference 2.5.2-229). Cramer (Reference 2.5.2-207) concludes that, although none of the three alternative sources can be eliminated, the Woodstock fault and vertical strike-slip alternatives better explain the 1886 damage observations than Chapman et al.'s (Reference 2.5.2-204) west-dipping fault.

Marple and Hurd (Reference 2.5.2-230) evaluated lidar and aerial photo data in the Summerville area and identified several topographic and tonal lineaments that they suggest are related to active tectonic deformation. These features include a 40-km-long, east-northeast-trending lineament near Woodstock fault, a 17-km-long, east-northeast-trending lineament near Middleton Place, and several east-west-trending scarps.

Shah et al. (Reference 2.5.2-231) combine interpretation of a new aeromagnetic dataset from coastal and central South Carolina with observations from seismic reflection studies and other information to identify possible seismogenic structures in the Charleston seismic zone. They identify evidence for east-southeast-trending lineaments that they interpret as Mesozoic faults in the South Georgia Rift. They note that these features are favorably oriented to be reactivated in the current stress regime, but that they appear too short (<20 km) to produce **M**~7 earthquakes. They also identify northeast-trending lineaments interpreted as inherited Paleozoic structures and note that these features appear long enough to produce **M**~7 earthquakes, but that transpressive slip would be required.

The new information on fault geometry and style indicates that changes to the CEUS-SSC model are required to account for a broader range in fault orientations, dips, and mechanisms. Revisions to the Charleston RLME source for use in the SRS PSHA are described below in Subsection 2.5.2.2.5.4.2. These same revisions are adopted for use in the CRN Site PSHA.

Recurrence: The recurrence intervals of large-magnitude earthquakes in the Charleston RLME source are based on the 1886 earthquake and the ages of large prehistoric earthquakes inferred from liquefaction features preserved in the geologic record. In the CEUS-SSC, when “In cluster”, these data indicate a weighted mean recurrence of about 580 years over the past approximately 2,000 years of record, and a weighted mean recurrence of about 1,730 years over the past approximately 5,500 years of record. Greater weight (0.8) is given to the recurrence derived from the shorter period than the longer period (0.2) because of concerns that the longer-period record is more likely to be incomplete (Figure 2.5.2-23R). No new paleoliquefaction age data are available that post-date the CEUS-SSC and that would change the interpreted number or timing of events in the Charleston RLME.

The CEUS-SSC includes two alternative models for large-earthquake recurrence of the Charleston RLME source: (1) the Poisson (time-independent) model; and (2) the Brownian Passage Time or “renewal” (time-dependent) model. The Poisson model assumes that the average time between events is known, but the exact timing of events is independent of the time since the last and previous events. A renewal model for the occurrence probability of earthquakes is appropriate when the data suggest a more periodic recurrence behavior than is implied by the Poisson model. Renewal models typically are used where a fault is subjected to quasi steady-state loading, such as may occur in a plate boundary setting.

In the CEUS-SSC, much greater weight was given to the Poisson model alternative. For the Narrow source zone, the Poisson model is assigned a weight of 0.9 and the renewal model is assigned a weight of 0.1. For the Regional and Local source zones, full weight (1.0) is given to the Poisson model.

Faults in the Charleston RLME are poorly understood. The fault source of the 1886 earthquake has not been conclusively identified, and it remains unclear whether the same fault or a different fault or faults produced the paleoliquefaction features observed in coastal South Carolina. If one fault is responsible for all the RLME events, then greater weight on the renewal model may be warranted. However, if different faults are responsible for different RLME events, then each fault may have its own “clock”, and the composite of their rupture histories may be better approximated as a Poisson process.

For use in the SRS PSHA, increased weight was assigned to the renewal model of earthquake recurrence, as described below in Subsection 2.5.2.2.5.4.2. These same revisions are adopted for the CRN Site PSHA (Reference 2.5.2-265).

2.5.2.2.5.4.1 New Information that Post-Dates the SRS Augmented SSHAC Level 2 Study

Several new studies on the Charleston seismic zone post-date the SRS augmented SSHAC Level 2 study (Reference 2.5.2-198), but none requires changes to the characterization of the

Charleston RLME source for use in the CRN Site PSHA (Reference 2.5.2-265). Below we briefly summarize selected post-SRS Charleston studies.

Pratt et al. (Reference 2.5.2-232) presents reinterpreted seismic reflection profiles, reprocessed older aeromagnetic data, and new ground-penetrating radar data to identify faults that deform Cretaceous and younger Coastal Plain strata in the epicentral area of the 1886 earthquake. Lead author Thomas Pratt shared much of this information with the SRS SSC TI Team by providing a preprint of this manuscript and by participating in the augmented SSHAC Level 2 Workshop for the SRS project. As a result, the key information in the Pratt et al. (Reference 2.5.2-232) paper was evaluated and integrated into the SRS SSC.

Shah et al. (Reference 2.5.2-232) used new, high-resolution aeromagnetic data, previous borehole logs, and reprocessed seismic reflection profiles to image subsurface structures and evaluate recent fault activity in the Charleston seismic zone. Lead author Anji Shah also participated in the augmented SSHAC Level 2 Workshop for the SRS project and shared much of this information with the SRS SSC TI Team.

Bilham and Hough (Reference 2.5.2-234) developed an elastic deformation model for the 1886 earthquake based on the sparse available constraints on coseismic deformation. Their preferred model yields an estimated **M** 7.3 for the 1886 earthquake, which is consistent with, but on the high side of, the CEUS-SSC range of **M** 6.7–7.5 for the Charleston RLME. Their preferred model includes rupture on a west-dipping reverse fault with 6.5 ± 0.3 m of dextral slip and 2 ± 0.5 m of reverse slip below 450-m depth.

In a follow-on paper, Bilham and Hough (Reference 2.5.2-234) used documented disturbances of three railroad lines in the Charleston area to investigate the 1886 earthquake and to question the commonly held belief that William Wilson’s famous photograph of deformed railroad tracks near Rantowles records surface deformation above subsurface dextral slip or as the result of thrust faulting (e.g., (Reference 2.5.2-232). This is consistent with the CEUS-SSC characterization of the Charleston RLME, which allows for considerable uncertainty in the source of the 1886 and prehistoric earthquakes in the area.

Hough and Bilham (Reference 2.5.2-236) investigated archival sources of information on the 1886 earthquake, especially Earle Sloan’s detailed geological field observations. Hough and Bilham ((Reference 2.5.2-236) point out that Sloan’s observations are an invaluable source of information on the earthquake, but that his reports include some data entry, transcription, and other errors. Hough and Bilham ((Reference 2.5.2-236) also speculate that Sloan may not have been in the Charleston area during the mainshock and the following week, and that he may have relied on some secondhand information in compiling his reports.

2.5.2.2.5.4.2 Summary of Changes to CEUS-SSC

Based on review of data that post-date the LCI (Reference 2.5.2-198) characterization of the Charleston RLME for the SRS, it is concluded that the SRS characterization of the Charleston RLME is appropriate for use at the CRN Site and that no additional changes are needed

(Reference 2.5.2-265). Revisions to the CEUS-SSC's Charleston RLME source for use in the CRN PSHA are summarized in Table 2.5.2-16R and Figure 2.5.2-29R and include the following:

- Replace the "Narrow" source geometry with a new "1886 Rupture" source geometry that represents Chapman et al.'s (Reference 2.5.2-204) hypothesized source of the 1886 earthquake. The Poisson and renewal recurrence models are equally weighted in this "fault-like" source.
- Increase weight on the renewal recurrence model from 0.0 to 0.1 for the Local zone. A weight of 1.0 on the Poisson model is retained in the larger Regional zone.
- For all three Charleston source zones, increase the range of permissible rupture strikes, dips, and fault styles. The overall northeast-oriented elongation of the Local and Regional zones is retained, reflecting the northeast-oriented elongation of the isoseismals from the 1886 earthquake and the regional structural grain.
- Zone boundaries for the 1886 Rupture and Local zones are leaky, such that ruptures that initiate within the zone are allowed to extend beyond the zone boundaries.

2.5.2.2.6.1.3 ETSZ Mmax Sensitivity Studies

Insert the following after the last paragraph of ESPA SSAR Section 2.5.2.2.6.1.3:

An additional sensitivity study was performed as part of the SSHAC Level 2 evaluation for the Y-12 site (Reference 2.5.2-150). This hazard sensitivity analysis was performed based on the postulated Dandridge-Vonore fault zone (DVFZ) within the ETSZ (Subsection 2.5.2.2.5.1). A 110-km-long "Quaternary fault corridor," the DVFZ was proposed by Reference 2.5.2-216 and Reference 2.5.2-217 based on limited geologic field observations and an apparent seismicity alignment. The input parameters for the sensitivity analysis of DVFZ were taken from Reference 2.5.2-218. The Mmax values and corresponding weights for the DVFZ were 6.0 (0.2), 6.5 (0.5), and 7.0 (0.2). The slip rates and associated weights were 0.001 mm/yr (0.45), 0.01 mm/yr (0.45), and 0.1 mm/yr (0.1). In addition, a probability of activity of 0.1 was assigned to the fault.

The results of the sensitivity analysis indicated that addition of the postulated DVFZ with the range of the input described above, did not significantly increase the hazard at the Y-12 site.

2.5.2.2.6.2 Earthquake Recurrence Rates

Insert the following after the last paragraph of ESPA SSAR Section 2.5.2.2.6.2:

As part of the Y-12 PSHA, a statistical test was performed to determine whether the new data in the Y-12 updated catalog (i.e., main events that occurred between 1/1/2009 and 12/31/2018) require recalculation of recurrence parameters for the Mmax and Seismotectonic distributed seismicity zones. The test was performed for those distributed seismicity zones that affect seismic hazard at the Y-12 site (Reference 2.5.2-150). The statistical analysis was performed to determine whether the rates of **M** ≥ 2.9 and **M** ≥ 3.5 earthquakes in the time period between 2009 and 2018 were consistent with predictions from the CEUS SSC recurrence parameters. The test

was performed for a circular area within 320 km of the Y-12 site, which is similar to the CRN site region. Details of the statistical test were given in Reference 2.5.2-150. The results of the test did not conclusively require recalculation of the recurrence parameters, in part because the **M** 2.9-3.6 range has a low weight in the CEUS SSC recurrence methodology. The recurrence parameters, however, were recalculated using the Y-12 updated catalog for the distributed source zones that make significant contributions to seismic hazard at the Y-12 site (namely, PEZ-N, NMESE-N, STUDY-R, PEZ-W, MESEW, MIDC-A, IBEB, RR, ECC-AM, and MESE-N). Recalculation of the recurrence parameters for the Y-12 site followed the CEUS SSC methodology.

2.5.2.3 Correlation of Seismicity with Seismic Sources

Renumber Figure 2.5.2-18 to Figure 2.5.2-18R in EPSA SSAR Section 2.5.2.3.

Renumber Figure 2.5.2-19 to Figure 2.5.2-19R in EPSA SSAR Section 2.5.2.3.

Renumber Figure 2.5.2-22 to Figure 2.5.2-22R in EPSA SSAR Section 2.5.2.3.

2.5.2.4 Probabilistic Seismic Hazard Analysis and Controlling Earthquakes

2.5.2.4.1 CEUS SSC Model Implementation

Delete the second, third, fourth, and fifth bullets in ESPA SSAR Section 2.5.2.4.1.

2.5.2.4.2 Ground Motion Models

Replace ESPA SSAR Section 2.5.2.4.2 with the following:

The ground motion models developed by the Next Generation Attenuation for Central and Eastern North America project (NGA-East) (Reference 2.5.2-221) were used in the hard rock PSHA for the CRN site (Reference 2.5.2-265).

As part of the Y-12 PSHA, a SSHAC Level 2 process was used to compile and evaluate new information and data that were potentially relevant to ground motion characterization in the Y-12 site region, which is essentially equivalent to the CRN site region. The study compiled ground motion data since 2011 for comparison to the NGA-East model, interviewed Resource and Proponent experts to learn of new data, models, and methods, reviewed new or updated GMMs, and compiled and reviewed other information potentially relevant to ground motion characterization in the site region. Based on their evaluations of the new information, the Y-12 Ground Motion Technical Integration Team concluded that the NGA-East GMM remains applicable for the calculation of basement rock ground motions without modifications or revision (Reference 2.5.2-150).

Crustal GMMs for tectonically active regions like the western U.S. are empirical in nature and derived from strong motion data from such areas as California, Taiwan, Japan, and Italy. In

contrast, few usable strong motion records exist for earthquakes in the Central and Eastern North America (CENA). Thus, GMMs for the CENA have been developed, in large part, using seismological-based numerical models. During the past decade, ground motion models for the CENA have been derived using three different approaches: the stochastic method, the Green's function method, and the complex/empirical source method.

The Pacific Earthquake Engineering Research Center (PEER) developed a new ground-motion characterization (GMC) model applicable for use in Central and Eastern North America (CENA, east of approximately 105 degrees west) through the Next Generation Attenuation for Central and Eastern North America project (NGA-East) (Reference 2.5.2-221). The GMC model consisted of two parts for use in a PSHA:

- A set of new GMMs for the median ground motions and their associated weights in the associated logic-trees.
- A set of new models for the aleatory standard deviations of ground motion, and their associated logic trees.

The final results and models of NGA-East were developed under the framework of the Seismic Senior Hazard Analysis Committee (SSHAC) (Reference 2.5.2-42; Reference 2.5.2-44) Level 3.

The NGA-East GMC is to be used in conjunction with the CEUS SSC products (Reference 2.5.2-1). The CEUS-SSC Project was also conducted under the SSHAC Level 3 framework; thus, having the GMC component of the NGA-East under SSHAC Level 3 framework ensured that both projects are of the same high-quality level for the end-uses.

The NGA-East ground-motion database (Reference 2.5.2-181) included the two- and three-component ground-motion recordings from numerous selected events (**M** > 2.5, distances up to 1500 km) recorded in the CENA region since 1988, up to December 2011. The database contains over 29,000 records from 81 earthquake events and 1379 recording stations. The events included "mainshocks," "aftershocks," and tectonic events, as well as potentially induced events (PIEs). The NGA-East database constitutes the largest database of processed recorded ground motions in stable continental regions (SCRs).

The NGA-East Project provided the best estimate of the distribution (median and standard deviation) of RotD50 (Reference 2.5.2-237) horizontal ground motions for horizontal peak ground acceleration (PGA), peak ground velocity (PGV), and 5%-damped pseudo-acceleration response spectra (PSA) for oscillator periods ranging from 0.01 to 10 sec on reference "hard-rock" site condition. The reference site conditions were defined by the NGA-East Geotechnical Working Group as corresponding to a V_S of 3000 m/sec and a kappa (κ) of 0.006 sec (Reference 2.5.2-238; Reference 2.5.2-239). The significance of the reference rock definition was that it represents the site condition for which ground motions will be predicted using the GMMs, and it represents the site condition to which site amplification factors are referenced (i.e., site amplification is unity for reference rock).

Final models in NGA-East are applicable to **M** 4.0 to 8.2 range, and for distances up to 1500 km from earthquakes source, using rupture distance as a distance metric. The final median

ground-motion logic tree consists of 17 branches, each corresponding to a GMM with a weight assigned.

The NGA-East Project evaluated regions of different geologic and tectonic settings in the CENA. The regions are the Central North America (CNA), the Appalachian Province (APP), the Atlantic Coastal Plain (ACP), and the Gulf Coast/ Mississippi Embayment Region (GCR). Each region is described by a statistically representative crustal seismic velocity-depth structure and Q-factor model. The crustal structural models are for very hard rock conditions and do not include any sediments. The ground motion analyses for different regions demonstrates that there are two distinct attenuation groups:

- Mid-Continent region (MCR): Central North America, Appalachians, and the Atlantic Coastal Plain.
- Gulf Coast Region (GCR): Gulf Coast including the Mississippi Embayment.

The GCR was found to clearly belong to a separate attenuation group. This result agrees with previous analyses that have found that the GCR has unique attenuation characteristics. The NGA-East base median GMMs are defined for the MCR. Adjustment models for the GCR are developed in the NGA-East Project. The site is situated within the GCR.

In addition to regionalization, the NGA-East Project developed adjustment models for source depth and hanging-wall effects. The source-depth adjustment accounts for depth dependence of the stress parameter. The hanging-wall adjustment accounts for the increase in ground motions at sites located above dipping earthquake ruptures compared to what would be expected at sites located at the same rupture distance but on the footwall side of the rupture.

In NGA-East GMC, standard deviation models are provided for site-specific analysis (single-station standard deviation) and for general PSHA applications (ergodic standard deviation). PSHA studies typically aim to evaluate the hazard at a single site. This requires characterizing the ground motion (median and variability) at the particular site due to the future occurrence of different earthquakes. Since repeated recordings at the site of interest are usually not available, the ergodic assumption is adopted, whereby the ground-motion variability over different sites and source regions is assumed applicable to an individual site. In such cases, the use of the ergodic assumption is valid as the PSHA is typically concerned with rare events with the likelihood of repeated occurrences being very low. More recently, the availability of repeated recordings at individual stations in ground-motion databases allowed for the estimation of the site-to-site variability and for removing it from the ground-motion aleatory variability. This led to a reduced aleatory variability as observed in previous studies (e.g., Reference 2.5.2-165; Reference 2.5.2-240). The application of the single-station approach, however, requires adjusting the median GMMs from representing average site conditions in the dataset used to develop the models to become site-specific. Site-specific adjustments of the median GMMs can be done using empirical ground-motion recordings when available at or near the site of interest or as part of the more commonly used analytical site response studies. The epistemic uncertainty resulting from the limited knowledge of the site-specific parameters and adjustment factors needs to be properly accounted for as part of the single-station approach.

In addition to the reduction in aleatory variability, the use of single-station sigma has multiple advantages. It allows for proper identification of the various components of ground-motion variability where some of the apparent randomness can be transformed to epistemic uncertainty. With the acquisition of additional data, this epistemic uncertainty can, in theory, be removed or decreased. Moreover, the use of single-station sigma has the advantage of avoiding double counting of the uncertainty in cases where the ergodic sigma is used and a site-specific response study performed. In such cases, the double-counting of the uncertainty is the result of the site-to-site variability being part of the total ergodic sigma, and the uncertainty in the site amplification factors are also captured as part of the site response study.

Nine single-station and ergodic sigma models were developed which represent the discrete approximations of the three continuous distributions of sigma models. To reduce the computational burden in hazard analyses resulting from the use of nine alternative sigma values, the three continuous distributions of the sigma models along with their weights are represented by a composite sigma model. The composite sigma model is then discretized into a three-point distribution. Three discrete points selected at the 5th, 50th, and 95th percentiles. The distributions for sigma show only a small degree of skewness, and the nominal weights of 0.185, 0.63, and 0.185 on the 5th, 50th, and 95th percentiles, respectively, produce values for the mean and standard deviation of σ that adequately represent those computed from the continuous distribution.

The NGA-East Project adopted two alternatives to represent the shape of ground-motion residuals: traditional lognormal distribution with a weight of 0.2 and a mixture of two normal distributions with weight of 0.8. The mixture model consists of an equally weighted mixture of two normal distributions, with one component having 0.8 times the normal sigma and the other component having 1.2 times the normal sigma.

The NGA-East team considered the CENA single-station sigma and total ergodic sigma models are applicable to both MCR and GCR. For this study, the full NGA-East median GMMs logic (17 models with associated weights) are used along with the logic tree given for single-station aleatory standard deviation.

For the Idaho National Laboratory (INL) SSHAC Level 3 project (Reference 2.5.2-260) GMC study and given the strong evidence of heavy tails and the improved performance of the mixture model in capturing the tails of the distribution, the mixture model was adopted with a weight of one. The normal distribution was not retained because it is not supported by statistical evidence. For this project, the mixture model with a weight of one was adopted and the normal distribution is excluded.

Moreover, the INL GMC TI team evaluated the spatial correlation of the ground-motion residuals observed and evaluated in other studies including Jayram and Baker (Reference 2.5.2-261 and Reference 2.5.2-262), Shahi et al. (Reference 2.5.2-263), and GeoPentech (Reference 2.5.2-264). They concluded that the ground-motion residuals are indeed spatially-correlated, and this correlation results in a small bias in the total single-station sigma. To account for the bias a larger weight was given to the high branch of the single-station sigma. INL (2022) study adopted weights of 0.15, 0.55, and 0.3 on low, central, and high branches of the

NGA-East single-station sigma. For this project, the same modified weights are applied to the low, central, and high branches of the NGA-East single-station sigma.

Ramos-Sepúlveda *et al*. (Reference 2.5.2-241) investigated whether the NGA-East GMMs for the CEUS reference hard-rock condition of 3000 m/sec and the site amplification models developed by Stewart *et al*. (Reference 2.5.2-242) and Hashash *et al*. (Reference 2.5.2-243), when used in tandem, are compatible with an expanded CENA ground-motion dataset relative to that used in the NGA-East Project. The expanded dataset includes recordings in CENA from November 2011 (end date of NGA-East data curation) to April 2022. While expanded, the range of magnitudes in the database remains limited (**M** ~ 4.0 to 5.8), hence their focus was mainly to assess mean model misfit within the range of the data, rather than scaling relationships that are also important for hazard applications. They evaluated the need for model adjustments to fit the available data, while leaving source and path scaling as-is.

They computed residuals using the 17 NGA-East GMMs and computed mean misfits using three subsets of the CENA data that reflect within-CENA regional variations in ground-motion attributes:

1. Non-TOK / Non-CP: Events and sites within Texas-Oklahoma-Kansas (TOK) and the Coastal Plains (CP) are excluded.

2. Non-TOK: All non-TOK events are considered including CP. No TOK events are considered.

3. Partial TOK: All non-TOK events are considered. Within TOK, random events were selected so that the event density (number of events per area) is consistent with other parts of CENA.

Ramos-Sepúlveda *et al.* (Reference 2.5.2-241) considered the 17 alternative NGA-East GMMs and three data selection criteria to compute the misfit terms. Various weighting combinations were considered for data selection, including equal weighting and weighting that gives preference to the non-TOK/non-CP data set. Ultimately, the recommended weights were 0.2 for the non-TOK set, 0.2 for the partial TOK set, and 0.6 for the non-TOK/non-CP set. All sites were considered in the development of the model adjustment factors presented in this section. They provide adjustment factors to the NGA-East GMMs and their epistemic uncertainties.

Ramos-Sepúlveda *et al*. (Reference 2.5.2-241) concluded that two factors potentially influence these misfits: (1) differences in the site amplification models used to adjust the data to the reference condition during NGA-East GMM development relative to CENA amplification models developed by Stewart *et al*. (Reference 2.5.2-242) and Hashash *et al*. (Reference 2.5.2-243), and (2) potential bias in simulation-based factors used to adjust ground motions from the hard-rock reference condition to a V_{S30} 760 m/sec condition. They provided adjustment factors and their epistemic uncertainties and discussed implications for applications. These adjustment factors were adopted in this study.

For the 2023 NSHM, the USGS included the Ramos-Sepúlveda *et al*. (Reference 2.5.2-241) adjustments with 0.5 weight (Reference 2.5.2-244). This decision was due to the recency of observations of misfits from CEUS GMMs and the USGS desire for greater understanding of the causes of this effect, as well as broader discussions regarding use of these adjustments. The

USGS agreed that these data are predominantly from small magnitudes and that there may be effects that would differ for larger magnitudes, which was part of the motivation for the lower weight. For this project, it was decided to follow the same approach. Hence, for the hazard calculations, the following logic-tree weights were used:

- 0.5: NGA-East GMMs as published (no adjustment)
- 0.5: NGA-East GMMs with adjustment factors given in Ramos-Sepúlveda et al. (2024).

2.5.2.4.3 Probabilistic Seismic Hazard Analysis and Deaggregation

Replace the second sentence of the first paragraph of ESPA SSAR Section 2.5.2.4.3 with the following:

The calculation of rock seismic hazard used the CEUS SSC seismic source characteristics with modifications described in Section 2.5.2.2.4.1, the NGA-East ground motion models (Reference 2.5.2-221) with adjustments (Reference 2.5.2-241) updated seismicity files that include the effect of recent seismicity on background sources and corrected and updated Mmax distributions for some of the background sources (Reference 2.5.2-265).

2.5.2.4.3.1 Seismic Sources

Replace the fourth sentence in the second paragraph of ESPA SSAR Section 2.5.2.4.3.1 with the following:

All background sources are represented with 24 sets of annual activity rates and *b*-value parameters for each source.

Replace the last paragraph of ESPA SSAR Section 2.5.2.4.3.1 with the following:

As described earlier, updates were made to the CEUS SSC Mmax and recurrence parameters for some of the source zones. The updates are as follows.

Updated a- and b- values based on the Y-12 updated earthquake catalog were used for the following sources:

1. Non-Mesozoic and younger extended prior-narrow
2. Mesozoic and younger extended prior-wide
3. Study Region
4. Paleozoic Extended Crust-narrow
5. Paleozoic Extended Crust-wide
6. Mesozoic and younger extended prior-narrow

7. Midcontinent-Craton alternative A

8. Extended Continental Crust-Atlantic Margin

9. Illinois Basin Extended Basement

10. Reelfoot Rift

Corrected Mmax distributions from EPRI were used for the following sources:

1. Paleozoic Extended Crust-narrow

2. Paleozoic Extended Crust-wide

3. Midcontinent-Craton alternative A

4. Midcontinent-Craton alternative B

5. Midcontinent-Craton alternative C

6. Midcontinent-Craton alternative D

7. Extended Continental Crust-Atlantic Margin

8. Illinois Basin Extended Basement

As discussed in Section 2.5.2.2.5.3.3, the New Madrid Fault System RLME was revised.

2.5.2.4.3.2 Seismic Hazard Results

Replace ESPA SSAR Section 2.5.2.4.3.2 with the following:

Seismic hazard results for hard rock for the CRN site were computed for 23 frequencies and PGA (Reference 2.5.2-265). Mean and fractile rock hazard curves for seven representative frequencies (0.5, 1, 2.5, 5, 10, 25 Hz and PGA) are shown in Figure 2.5.2-30R through Figure 2.5.2-36R. Mean rock hazard curves for all 23 frequencies and PGA are provided in Table 2.5.2-17R. The contributions to rock hazard from the total of all background sources and each individual RLME source (Charleston, Commerce, ERM-N, ERM-S, Marianna, NMFS, and Wabash Valley) for 1 Hz and 10 Hz are plotted in Figure 2.5.2-37R and Figure 2.5.2-38R. The total mean hazard for 1.0 Hz is dominated by the NMFS and the background sources for AFEs of 10^{-3} and 10^{-4} (Figure 2.5.2-37R). The relative contribution to the total hazard from background sources increases with decreasing AFEs, such that at 10^{-5} AFE, the hazard is completely dominated by the background sources. The total mean hazard for 10 Hz is dominated by the background sources (Figure 2.5.2-38R).

Contributions to 1 Hz and 10 Hz hazard by individual background sources only are plotted in Figure 2.5.2-39R and Figure 2.5.2-40R. The dominant background source zones are PEZ-N, Study-R and NMESE-N, which are host zones for the CRN site.

Sensitivity of the 10 Hz rock hazard to the 17 NGA-East median ground motion models (GMMs) unadjusted and adjusted for bias as described in Section 2.5.2.4.2 is shown on Figure 2.5.2-41R and Figure 2.5.2-42R. Similarly, Figure 2.5.2-43R and Figure 2.5.2-44R show the sensitivities of the 1 Hz rock hazard to the 17 NGA-East GMMs.

Figure 2.5.2-45R shows the mean total rock hazard curves for seven representative frequencies (PGA (200 Hz), 25, 10, 5, 2.5, 1 and 0.5 Hz). The hazard curves all extend to 10^{-7} AFE or lower. Mean total rock hazard curves for all 23 frequencies and PGA are provided in Table 2.5.2-17R.

2.5.2.4.3.3 Deaggregation and Uniform Hazard Response Spectra

Replace Table 2.5.2-17 with Table 2.5.2-18R in the first paragraph of EPSA SSAR Section 2.5.2.4.3.3.

Replace third and fourth paragraphs of ESPA SSAR Section 2.5.2.4.3.3 with the following:

Deaggregation of the hard rock hazard results was performed at several spectral periods (Reference 2.5.2-265). For the CRN site PSHA, low-frequency (LF) and high-frequency (HF) deaggregation plots for each MAFE are shown in Figure 2.5.2-46R through Figure 2.5.2-51R. The LF plot represents the average deaggregation of the 1 and 2.5 Hz spectral acceleration hazard; the HF plot represents the average deaggregation of the 5 and 10 Hz spectral acceleration hazard.

For both high and low frequencies, the seismic hazard at the CRN Site for the ESPA is noticeably dominated by the background seismic sources within 100 km or less (Figure 2.5.2-46R through Figure 2.5.2-51R). For the low frequencies, seismic sources located about 400 to 500 km from the site, likely the NMFS RLME, have a significant contribution, as suggested in Figure 2.5.2-37R. The NMFS RLME contributes between 45 and 50 percent at 10^{-4} AFE, between 20 and 45 percent at 10^{-5} AFE and approximately 20 percent at 10^{-6} AFE.

Replace the fourth sentence in the fifth paragraph of ESPA SSAR Section 2.5.2.4.3 with the following:

In addition, the LF hazard contains contributions from distant sources, dominated by the NMFS RLME.

Replace the sixth, seventh and eight paragraphs of ESPA SSAR Section 2.5.2.4.3.3 with the following:

Based on the LF and HF deaggregation shown in Figure 2.5.2-46R through Figure 2.5.2-51R, the mean deaggregated magnitude and distance are calculated. Table 2.5.1-18R provides the controlling earthquake magnitudes and distances for a suite of eleven mean AFEs ranging from 10^{-2} to $2x10^{-7}$. Durations for these 11 events are also provided in Table 2.5.1-18R.These magnitudes and distances are used to develop input control motions for site response analyses at the CRN Site.

The hazard rock hazard results were interpolated to calculate UHRS for a suite of AFE (Reference 2.5.2-265). UHRS for 10^{-4}, 10^{-5} and 10^{-6} are shown on Figure 2.5.2-52R. The UHRS at 10^{-3}, 10^{-4}, 10^{-5} and 10^{-6} AFE are provided in Table 2.5.2-19R.

2.5.2.5 Seismic Wave Transmission Characteristics of the Site

Replace the second sentence of the first paragraph of ESPA SSAR Section 2.5.2.5 with the following:

The site amplification factors are used in determination of the FIRS, PBIRS, and PBSRS for the CRN Site. The seismic wave transmission characteristics of the CRN Site, presented in the CRN Site ESPA (Reference 2.5.2-196), were computed by considering a plant parameter envelope (PPE) at Locations A and B (Figure 2.5.4-11). The computations, as presented in this subsection, have been revisited and updated to incorporate the BWRX-300 SMR.

Replace the second paragraph of ESPA SSAR Section 2.5.2.5 with the following:

In order to examine the potential impacts of non-vertically propagating waves due to the dipping stratigraphy beneath the CRN Site (about 33 degrees) on the site response analysis results, a series of sensitivity analyses using an expanded version of the computer code SASSI (System for Analysis of Soil Structure Interaction) are developed and presented in the CRN Site ESPA (Reference 2.5.2-196). Performing site-specific sensitivity evaluations on the potential effects of non-vertically propagating seismic waves is also one of the requirements of Section 5.3.3 of NEDO-33914-A (Reference 2.5.2-134). The results of the 2D sensitivity analysis are presented Subsection 2.5.2.6 in the CRN Site ESPA (Reference 2.5.2-196).

Replace the third paragraph of ESPA SSAR Section 2.5.2.5 with the following:

A geologic cross-section at the site that illustrates the depth to Precambrian rock, drawn perpendicular to the strike direction, is shown on Figure 2.5.1-63. The final plant surface grade at the site has been set at Elevation 814.5 ft. The planned bottom of the foundation in the vertical shaft for Reactor Building (RB) is taken at Elevation 699.5 ft, which is at a higher elevation compared to the foundation level considered in the ESPA (i.e., 683 ft). The new proposed layout of the BWRX-300 SMR at the CRN Site is located in the vicinity of Location A. In fact, the proposed location of the RB vertical shaft is surrounded by the same borings that were used to develop the subsurface seismic wave velocity profile for Location A in the ESPA. As described in Section 2.5.4.5.1, the base-case V_S profile in the ESPA was developed with data from boreholes that were within or just outside Location A (within 100 ft). Boreholes whose data were used in developing the V_S profile on Figure 2.5.4-14 fall within the footprint of the layout of the BWRX-300 SMR or in its close proximity and approximately envelope the RB. In fact, boring MP-101 borders the Service Building, MP-102 is adjacent to the RB and Turbine Building, MP-111 is located within the footprint of the Service Building. Borehole MP-120 is slightly to the East (considering the plant North) of the Radwaste Building. Moreover, the top of the competent rock at the BWRX-300 SMR location was considered similar to the top of unweathered rock at Location A. It is recognized that the top of competent rock varies across the CRN Site, as shown in Figure 2.5.4-2R. Since the depth of the vertical shaft of the RB is expected to be around 115 ft

below the final plant grade elevation, the foundation elevation of the RB foundation (for FIRS) is noticeably below the top of unweathered rock. All elevations cited in this subsection are based on the North American Vertical Datum of 1988 (NAVD88).

Supplemental site-specific field exploration (References 2.5.2-227 and 2.5.2-228) and testing have been conducted to supplement the CPA for the selected GEH BWRX-300 SMR. The general guidance from Section 3.3.1 of NEDO-33914-A (Reference 2.5.2-134) were considered in developing this investigation plan for the GEH BWRX-300 SMR layout. These data were used to update the velocity profile at the CRN site underlying the BWRX-300 SMR.

The proposed layout of the BWRX-300 SMR at the CRN Site includes surface-founded structures around the vertical shaft of the RB. At this stage of the project, it is considered that these buildings will be constructed on deep foundations (drilled shafts). Considering the existing elevation at the site will be raised to the final plant grade elevation (i.e., Elevation 814.5 ft) using engineered fill, the generalized soil and rock profile at Unit 1 location consists of three strata: soil (including engineered fill on top of the existing fill and residual soil), in-situ weathered rock, and in-situ unweathered rock. The soil and weathered rock layers were not incorporated in the development of the amplification factors in the ESPA for the CRN Site (Reference 2.5.2-196); however, in the present analyses, they are included in the soil/rock column to develop the amplification factors at the final plant grade elevation. It is assumed that the horizontal extent of the engineered fill, to raise the existing surface elevation at the site to the final plant grade elevation, will be large enough to represent a reasonable 1D profile. Moreover, the potential impact of the deep foundations of the surface-founded structures on the dynamic properties of soil and weathered rock and subsequently amplification factors are examined, as presented in Subsection 2.5.2.5.9, by developing an equivalent uniform 1D soil and rock profile in a set of sensitivity analyses.

Delete the third sentence of the last paragraph of ESPA SSAR Section 2.5.2.5.

2.5.2.5.1 Base-case Site-Specific Geologic Profiles and Uncertainties

Replace ESPA SSAR Section 2.5.2.5.1 with the following:

A V_S base-case profile for the CRNS was developed for use in the SRA (Reference 2.5.2-265). This profile was extended by attaching the deep profile down to the Precambrian basement. This section describes the methodology for developing the V_S profiles.

Shallow Profile:

Geotechnical and geophysical tests were performed at the CRNS in both 2013 and 2023 to determine the site profile. The MP series borehole logging was conducted in 2013 (Reference 2.5.2-245) and the U1B series borehole logging in 2024 (Reference 2.5.2-228). Early Site Permit (ESP Part 2) (Reference 2.5.2-196) shows the summary tables for the 2013 data. In this study, new data are also added to update the summary tables. Table 2.5.2-20R shows the elevation and thickness of the shallow soil layers along with the depth to bedrock. The median of existing ground surface elevation is 799 ft (244 m). The existing fill and residuum layer is about

18 ft (5.5 m) thick with spatial variability. Likewise, the median bedrock depth is at 777 ft (237 m) elevation with a standard deviation of 0.2. The median thickness of gravelly soil layer between the residuum and hard rock is about 4 ft (1.21 m). This gravelly soil layer was referred to as partially weathered rock in previous reports (Reference 2.5.2-196; Reference 2.5.2-246). Table 2.5.2-21R shows the depth to the different layers of soil/rock considering the final ground elevation of 814.5 ft (248 m).

To develop the V_S profiles, Geovision Geophysical Services performed P-S logging (suspension) twice at the CRNS. Geovision (Reference 2.5.2-247) reported suspension measurements of P-wave (V_P) and V_S at approximately 1.64 ft (0.5 m) vertical intervals to the depth of penetration. At Location A, suspension logging was performed in seven borings: MP-101, MP-102, MP-111, MP-111PS, MP-120, MP-122PSA, and MP-122PSB. Two directional borings (PS-112 and PS-113) that were drilled at a nominal inclination of 28 degrees are excluded from this list. Geovision (Reference 2.5.2-248) report (Appendix IV of Reference 2.5.2-228) shows eight suspension logging test results namely U1B01, U1B02, U1B03, U1B04, U1B06, U1B07, U1B10, and U1B15. U1B15 which is outside of the footprint of the CRN Unit-1 building is not considered in this report. The suspension logging data are smoothed every three data points which is 4.92 ft (1.5 m) intervals of depth and plotted in Figure 2.5.2-53R. The lognormal mean of the suspension logging data for the rock profile was calculated and plotted in the same figure. MP-111PS, MP-122PSA, and MP-122PSB that show the shallow profile (containing soil) were excluded while calculating the lognormal mean of the rock profile.

The University of Texas at Austin (UT Austin) also recently performed downhole surveys and SASW at the site (Reference 2.5.2-249). Eight downhole surveys were conducted at the same location as the Geovision (Reference 2.5.2-248) suspension logging. SASW was conducted across three different linear surface arrays. Moreover, free-free resonant column testing was conducted to measure the V_S of core samples extracted from the site. All these results are summarized in Stokoe *et al*. (Reference 2.5.2-249) as shown in Figure 2.5.2-54R. Compared to the Geovision data, these data showed higher variability in the top 138 ft (42 m). Comparisons between V_S profiles from the SASW method, downhole seismic testing, and laboratory tests were made. The statistical analyses showed higher variability in the upper layers (COV as high as 0.76) and more uniform properties at depths greater than 138 ft (42 m) (COV less than 0.12). The results indicate a large difference between SASW and downhole velocity measurements (as much as 6,000 ft/sec (1829 m/sec)), where SASW is showing lower values in a range of about 40 to 140 ft depth (12.2 to 42.7 m). The boring logs found limestone in this depth range. Therefore, the low V_S (about 2,000 ft/sec (610 m/sec)) shown in SASW in this depth range is not realistic. Likewise, if the large impedance contrast shown in downhole test results is considered as the transition from soil to hard rock, the depth range for this transition is found to be from about 38 to 105 ft (11.6 to 32 m). However, as shown in Table 2.4.2-20, the boring logs show the depth of transition to hard rock is shallower (22 +/- 8 ft) considering the existing ground surface elevation is 799 ft (244 m). Hence, after an evaluation of all the available data, the Geovision suspension logging data were used to develop the rock V_S profile. The soil V_S profile was adopted from the boring log data shown in Table 2.5.2-20R and Table 2.5.2-21R following the V_S recommendations in ESP Part 2 (Reference 2.5.2-196) Table 2.5.4-11 (600 ft/sec (183 m/sec) for existing fill and residuum and 1870 ft/sec (570 m/sec) for gravelly soil). The V_S of new fill is

assumed to be 1000 ft/sec (305 m/sec) (Reference 2.5.2-250) considering a compacted granular fill.

Deep Profile:

Input ground motions used in the SRA were calculated for a hard rock site conditions of V_S 3,000 m/sec using the NGA-East GMMs. These models require a uniform hard rock site condition with V_S increasing with depth. Also, the effects of the alternating V_S layers beneath CRNS needed to be addressed in the SRA. Thus, the shallow V_S profile needed to be extended down to uniform hard rock. Beneath the CRNS, this coincides with the Precambrian basement at a depth of approximately 11,000 ft (3,352 m).

At depths below the shallow lognormal V_S profile where there are no measured V_S data, the geologic profile shown in Figure 2.5.4-16 was used to extend the profile. An average velocity was assigned to each geological unit down to and including the uppermost unit of the Knox Formation (Newala unit) based on the mean V_S shown in Table 2.5.4-16. Examination of the V_S profile for each unit showed generally constant V_S with depth, thereby a single mean V_S value for each unit was utilized. The lower and upper range base-case profiles will account for the epistemic uncertainty in the mean base-case profile. The mean V_S adopted for the Newala unit was used for the rest of the Knox unit (rounded up to 11,000 ft/s) due to their similar lithologies. Figure 2.5.4-16 shows the V_S profile down to the Newala unit.

Beneath the Knox unit, there are no data for the deeper units at the CRN Site, which include the Conasauga shale, Rome Formation sandstone, and Pumpkin Valley shale. These units repeat themselves with depth because of the overthrusting (Figure 2.5.4-13). V_S data were available for all three formations from the deep SASW surveys that were performed at WBN2 (Reference 2.5.2-172). At a depth of 500 ft, the Conasauga shale and Pumpkin Valley shale have measured V_S values of 6000 ft/s and 6000 to 7000 ft/s, respectively at WBN2. The Rome sandstone had measured values of 9000 to 10,000 ft/s at a depth of 1500 ft (Reference 2.5.2-172). An unconfined free-free resonant column (URC) test also measured a V_S of almost 9000 ft/s for a sample of Rome Formation (Reference 2.5.2-172, Appendix B). Although these V_S values are not site-specific, they likely are representative of the V_S for these units beneath the CRN Site at depths below the OYO surveys based on regional stratigraphic relationships.

To estimate the V_S of the units below depths of 500 to 1500 ft, a review was performed of the deep V_S profiles available in the literature that went down several kilometers. Based on the review, the generic V_S profile for CEUS hard rock developed by Boore and Joyner (Reference 2.5.2-266) was selected. No region-specific V_S profile information was available. Examination of the central and eastern U.S. V_S database compiled by PE&A support the use of the value of 6000 ft/s at a depth of 500 ft for the Conasauga shale and 9000 ft/s at a depth of 1500 ft for the Rome Formation and the Pumpkin Valley shale (Figure 2.5.4-13). The adjusted Boore and Joyner (Reference 2.5.2-266) generic profiles were then used to estimate the V_S for

the deeper units (Figures 2.5.4-18 and 2.5.4-19). Once Precambrian rock was reached, the V_S profiles were truncated at a V_S of 11,000 ft/s.

2.5.2.5.1.1 Epistemic Uncertainties in V_S

Replace ESPA SSAR Section 2.5.2.5.1.1 with the following:

For each best-estimate (BE) base-case profile, lower- and upper-range profiles (LR and UR, respectively) were calculated applying a factor of 1.28 to the best-estimate base-case V_S profiles (11.28 and 11.28, respectively) corresponding to an epistemic σln of 0.2, following the SPID (Reference 2.5.2-209). Below 541 ft (165 m) depth, where measured V_S data are not available, a factor of 1.57 was used corresponding to a σ_{ln} of 0.35 SPID (Reference 2.5.2-209). This calculation of lower- and upper-range profiles is consistent with the previous PSHA done for this site as described in AECOM (Reference 2.5.2-251). The best-estimate, lower-range, and upper-range profiles are weighted 0.4, 0.3, and 0.3, respectively, following the SPID (Reference 2.5.2-209). The upper-range profiles were truncated at a maximum V_S of 11,000 ft/sec (3,352 m/sec), the V_S of the Precambrian basement. The site profile is shown in Figure 2.5.2-55R. The details of the discretized site profiles are provided in Table 2.5.2-22R and Table 2.5.2-23R.

For randomization of V_S, aleatory variability is assigned to each layer in a depth-dependent manner per the SPID (Reference 2.5.2-209). Values range from σ_{ln} of 0.25 at the existing ground surface to 0.15 at and below a depth of 50 feet (15.2 m) and are interpolated above this depth. For the new fill layer, σ_{ln} of 0.15 was used. Realizations of V_S in each layer are restricted to $\pm 2\sigma_{ln}$ and are correlated following recommendations of the SPID (Reference 2.5.2-209).

2.5.2.5.1.2 Unit Weights

Replace ESPA SSAR Section 2.5.2.5.1.2 with the following:

The unit weights were collected from the Table 2.5.4-21 in ESP Part 2 (Reference 2.5.2-196). Existing fill/residual soil which are mainly clayey/silty soil of usually high plasticity (CH, MH, ML) has a unit weight of 120 pcf. The gravelly soil layer which are mainly clayey/silty gravel (GC, GM) and in some cases poorly graded gravel with sand (GP) has a unit weight of 140 pcf. The Benbolt Formation beneath the site, mostly consisted of limestone and siltstone, was found to have a unit weight of 168 pcf. Finally, the new granular backfill has a unit weight of 135 pcf, which will consist of processed graded aggregate meeting the requirements of Type A aggregate (Reference 2.5.2-252) as mentioned in ESP Part 2 Section 2.5.4.5.3 (Reference 2.5.2-196).

2.5.2.5.2 Estimation of Kappa

Replace ESPA SSAR Section 2.5.2.5.2 with the following:

WSP (2023) developed an empirical equation to estimate kappa using kappa values estimated from earthquake recordings at five dams in the TVA region (not including the CRNS). The equation incorporates the time-averaged shear wave velocity in the top 100 m (V_{S100}) and the total thickness of shale units within the top 2 km of the crust (T_{Shale}). The model for estimating κ is as follows:

$$\ln(\kappa) = -2.958 - 0.2484 \times \ln(V_{S100}) + 0.1085 \times \ln(\max(T_{Shale}, 0.21)) \quad \text{Equation 2.5.2-8}$$

where the units of:

V_{S100} is m/s

T_{Shale} is m

κ is seconds

The standard deviation of ln(κ) is 0.36.

For the CRNS, 460 m of Conasauga shale is present in the top 2 km of the crust as shown in Figure 4-10 of AECOM (Reference 2.5.2-251) report. Therefore, a T_{Shale} value of 460 m is used such that Equation 2.5.2-8 produces a κ value of 0.0173 sec (where V_{S100} = 1213.2 m/s) (BE profile (Table 2.5.2-24R).

Following Appendix B of Reference 2.5.2-209, epistemic uncertainty in site kappa is represented by the 10th and 90th percentiles. Using sigma ln(κ) of 0.36, this results in multiplicative factors of 0.699 and 1.434 for the 10th and 90th percentiles, respectively. Assuming negative correlation between V_S uncertainty and kappa uncertainty, the 10th percentile κ is assigned to the 90th percentile V_S (UR profile) and the 90th percentile κ is assigned to the 10th percentile V_S (LR profile). Table 2.5.2-24R lists the resulting kappa values.

2.5.2.5.3 Dynamic Material Nonlinearity

Replace the last four paragraphs of ESPA SSAR Section 2.5.2.5.3:

The soil column for the site response analysis at the CRN Site consists of three general strata: soil (engineered fill on top of the existing fill and residual soil), in-situ weathered rock, and in-situ unweathered rock (Section 2.5.1.2). In this subsection the selection of modulus reduction and damping ratio curves that represent the nonlinearity of dynamic properties for these strata are discussed.

Resonant column and torsional shear (RCTS) tests were performed for the CRNS specimens in 2013 to determine appropriate dynamic material properties, shear modulus reduction and damping ratio curves (MRD curves) for CRNS soil (Reference 2.5.2-253). Two soil specimens were tested (MP111UD and MP122UDA) at two different confining pressure levels. In 2023, RCTS tests were conducted again on soil and rock specimens from CRNS by Stokoe *et al*. (Reference 2.5.2-254; Reference 2.5.2-255) from UT Austin. Three soil specimens (specimens 1, 2 and 3) were collected from different depths below ground surface and tested at three different confining pressure levels. All the old and new soil specimens show a similar trend of the MRD curves except for specimen 2 which was collected from a shallow depth of 6.5 ft (2 m). The results from this specimen are not considered, as it may have been more disturbed because it was extracted from a shallow depth. The MRD curves are plotted in Figure 2.5.4-56. The generic EPRI (Reference 2.5.2-136) clay curves are also shown in this Figure 2.5.2-54R for plasticity index (PI) =30 and PI=40. A lognormal mean is calculated which is referred as Clinch River soil. As this curve ends at low strain (0.025%), it is manually extended (shown with dashed black line) to higher strain levels based on the trend of the existing lognormal mean curve and the trend of the EPRI clay curves.

Resonant column (RC) tests were conducted (Reference 2.5.2-255) on ten rock core specimens collected from different depths at CRNS. Although they were tested at different confining pressure, the curves related to only the highest confining pressure were considered in this report. Stokoe *et al*. (Reference 2.5.2-255) recommended using the results from the highest confining pressure because all of the specimens had micro-cracks, and the increasing confining pressure tended to close the microcracks. Also, excluding the shallowest and deepest specimens, all the other specimens showed similar trends in the MRD curves. These two specimens were excluded from this report because the shallowest specimen may have been more disturbed by sampling/coring and the deepest specimen may be too stiff compared to the RC test apparatus to provide a reliable measurement. The MRD curves from all other specimens are plotted in Figure 2.5.2-57R and a lognormal mean is also calculated (referred as Clinch River rock). Similar to the Clinch River soil curve, this curve is also manually extended (shown with dashed black line) to higher strain levels based on the trend of the existing curve and the trend of the EPRI (Reference 2.5.2-136) rock curve. The EPRI rock curve (501-1000 ft) is also shown in Figure 2.5.2-55R.

Three equally weighted models for G/Gmax and damping are used to represent epistemic uncertainty in these properties at the CRNS (Table 2.5.2-22R and Table 2.5.2-23R) (Reference 2.5.2-265). In the shallow portion of the profiles (uppermost approximately 500 ft (152 m)), three material models (M1, M2, and M3) are used. M1 and M2 are appropriate generic models (Reference 2.5.2-209), while M3 uses the MRD curves from site specimens when available. If test results are not available for a layer (fill and gravelly soil), another generic curve is used for M3. For rock, the EPRI rock (501-1000 ft) modulus reduction and damping model was used for M1, while M2 is linear with damping equal to the low-strain damping of M1, while M3 again uses the curves from test results. Below about 500 ft (152 m), M1, M2, and M3 curves are linear with damping. The depth of 500 ft (152 m) is consistent with the SPID (Reference 2.5.2-209) and is not a strict cutoff. The material property change is made in the first layer that begins below that depth. Table 2.5.2-26R to Table 2.5.2-32R list the MRD curves used

at various levels of shear strain (%). The damping ratio for all curves will be capped at 15% in the SRA.

For randomization of dynamic material properties, aleatory variability in G/Gmax and damping is assigned to each material per the SPID (Reference 2.5.2-209). The SPID recommends σ_{ln} of 0.15 for G/Gmax at a strain of 0.03%, and σ_{ln} of 0.30 for damping at a strain of 0.03%, with correlation of -0.5. Realizations of V_S in each layer are restricted to $\pm 2\sigma_{ln}$ (Reference 2.5.2-265).

Delete ESPA SSAR Section 2.5.2.5.3.1 Linear Analyses.

2.5.2.5.3.1 Linear Analyses

Renumber ESPA SSAR Section 2.5.2.5.3.2 to Section 2.5.2.5.3.1 and Replace with the following:

2.5.2.5.3.1 Total Effective Kappa

The lower-range, best-estimate, and upper-range values for kappa at the CRN Site are estimated as 0.0248, 0.0173, and 0.0121 sec, respectively (Table 2.5.2-24R) (Reference 2.5.2-265). Following the recommendations in Keefer and Bodily 1983 (Reference 2.5.2-261) and SPID (Reference 2.5.2-139), the weights for the kappa branches are 0.3, 0.4, and 0.3 for the LR, BE, and UR estimates of kappa, respectively. It is noted that this weight scheme is different from the weights (0.2, 0.6, and 0.2) in the ESPA. To distribute damping throughout the V_S profiles BE, LR, and UR, the total effective kappa was used as a constraint for the sum of damping throughout the profiles. It is important to note the details of how the damping is distributed through the profiles, conditional on the total effective kappa, has a minor effect on the amplification (Reference 2.5.2-164). As such the damping (in terms of Q) may be made either constant with depth, increasing with depth due perhaps to increasing confining pressure (e.g. typical damping curves and Reference 2.5.2-167), or proportional to V_S. Lacking a physical basis for preference, proportional to V_S was used (References 2.5.2-168 and 2.5.2-155) as it accommodates confining pressure dependencies in a consistent manner.

Total effective kappa for each profile is determined by summing the contributions of the ground motion model (GMM) and each layer using assigned low-strain dynamic properties. The contribution to total effective kappa of the NGA-East GMM is 0.006 sec (Reference 2.5.2-221; Reference 2.5.2-239) Total effective kappa (in seconds) is therefore computed as

$$\kappa = 0.006 + \sum_{i=1}^{n} \frac{2 H_i D_i}{V_{S,i}} \qquad \text{Equation 2.5.2-9}$$

where:

H is the thickness of layer

---

i and *D* are low-strain damping

In this manner, the contribution of the shallow portion of each profile to total effective kappa is fixed by each model. Damping of the linear material in the deep portion of each profile is then set such that Equation 2.5.2-9 sums to the target kappa value. This is repeated for each combination of profile (best-estimate, lower-range, and upper-range) and material model (M1, M2, and M3). Damping in the deep portion of each profile is on the order of 0.37% or less. Resulting damping values are provided in Table 2.5.2-25R.

2.5.2.5.4 Capturing Site-Specific Geologic Column Properties, Uncertainties, and Correlations

Replace ESPA SSAR Section 2.5.2.5.4 with the following:

Addressing the epistemic uncertainties in the V_S profiles, site kappa, and MRD curves were previously discussed in Section 2.5.2.5.1.1, 2.5.2.5.2.1, and 2.5.2.5.3, respectively.

To provide an objective means of smoothing resonances that tend to be over-predicted by the vertically propagating V_S model in a one-dimensional profile (Reference 2.5.2-136) and, to a far lesser extent, to account for the aleatory variability in dynamic material properties that is expected to occur across a site at the scale of a typical facility, variability in the V_S profiles and other dynamic properties is incorporated. For the CRNS, random V_S profiles have been developed about the smoothed base-case, lower-range, and upper-range profiles (Reference 2.5.2-265).

A profile randomization scheme has been developed that varies layer velocity, depth to baserock, G/Gmax curves, and damping curves. The randomization of V_S is based on a correlation model developed from the statistical analysis of about 500 measured V_S velocity profiles (Reference 2.5.2-136; Reference 2.5.2-142). Depth to baserock is varied by plus or minus 20 percent using a uniform distribution. The standard deviations used in the randomization of V_S and degradation properties are generally based on the SPID (Reference 2.5.2-209). These randomization parameters reflect a minimum variability while providing for a realistic variation across footprint dimensions (several hundred feet) resulting in an objective smoothing of narrow resonances while preserving broad resonances yet not developing deep low-velocity zones that introduce artificial damping through wave scattering (scattering kappa).

For the V_S profile and the PBSRS control point, the depth to the top of the gravel layer (at 33.5 ft (10.2 m) below the ground surface) and rock (at 37.5 ft (11.4 m) below the ground surface) were also randomized using a normal distribution. The standard deviation used for this randomization is provided in Section 2.5.2.5.1.1. It should be noted that the depths to the top of the gravel and rock were not randomized for the PBIRS control point.

A total of 60 randomized profiles are generated for each base-case, lower-range, and upper-range profiles. Figure 2.5.2-58R shows the randomized V_S profiles for the best-estimate profile for the PBSRS control point. As mentioned above, the depths to the gravel and rock layers

were both randomized. Figure 2.5.2-59R shows the randomized V_S profiles for the best-estimate profile for the PBIRS and FIRS control points. For these cases, the depths to the gravel and rock layers were not randomized. Separate panels are shown for the top portion (left) and for the entire profile (right). Each panel shows the 60 randomized velocities (green), their geometric mean and ± two-sigma range (solid and dashed blue). In addition to the ± two-sigma range provided as input (dashed and dot-dashed blue). In addition to the ± two-sigma limits, the randomized velocities are not allowed to exceed 11,000 m/sec, which is the value assigned to Precambrian basement hard-rock at the base of each profile. A similar limitation is imposed at low velocities to maintain the geometric mean of the velocities close to the target value specified as input. Layer thicknesses are not randomized, as this will not have a significant effect on the mean and variability of amplification when velocities are also randomized.

2.5.2.5.5 Site Response Analysis

Renumber Equation 2.5.2-8 through 2.5.2-11 to 2.5.2-10 and 2.5.2-13 in ESPA SSAR Section 2.5.2.5.5.

2.5.2.5.5.2 RVT-Based Equivalent-Linear Site Response Approach

Replace the third paragraph to the end of ESPA SSAR Section 2.5.2.5.5.2 with the following:

The computational scheme employed to compute the amplification factors in this study uses an alternative approach employing RVT (Reference 2.5.2-156). In this approach, as embodied in the computer program TRANSAMP, Version 1.2 (Reference 2.5.2-256), the peak values using random vibration theory (RVT), or extreme value statistics are computed.

Inputs to TRANSAMP are as follows:

- Location of input and output motions within the site profile.
- Input (control) motions characterized by earthquake power spectra. In the program, the object motion must be specified by the user as bedrock outcrop motion in the form of Fourier amplitude spectrum.
- A vertical profile consisting of uniform plane-layer layers with specified thickness, seismic velocity, and density as a function of depth.
- Nonlinear dynamic properties of the material at the site, consisting of low strain damping, strain-dependent shear modulus and damping curves for each layer.

Input (control) motions must be calculated for input into the site response analysis that are representative of the earthquake magnitude and distance dominating the hazard at the desired rate of exceedance. The basis for the control motions are the magnitude and distances specified by the hazard deaggregation.

The LF and HF deaggregated magnitudes and distances (Table 2.5.1-18R) are used to develop a representation of the ground motion on baserock that is consistent with the hard rock PSHA for the CRN site (Reference 2.5.2-265). This representation consists of 22 response spectra and

their associated durations, covering a broad range of hazard-significant amplitudes (associated with an AFE range from 10^{-2} to 10^{-7}) and spectral shapes. Eleven of these spectra correspond to HF associated with nearby earthquakes and 11 to LF associated with more distant large-magnitude earthquakes in the RLME zones.

The HF spectrum for a given AFE is constructed as follows:

1. The spectral ordinates at and above 2.5 Hz all correspond to the same AFE from the rock hazard analysis (i.e., they correspond to the HF portion of the UHRS for that AFE).

2. A scenario spectrum is obtained by using the weighted mean of the NGA-East GMM amplitudes associated with the mean magnitude and distance obtained in the high-frequency (5 and 10 Hz) deaggregation (Table 2.5.1-18R).

3. The spectrum from Step 2 is truncated to remove ground motions above 2.5 Hz, then scaled so that it matches the UHRS at 2.5 Hz.

4. The HF spectrum at this AFE consists of the scaled scenario spectrum from Step 3 below 2.5 Hz, and the UHRS from Step 1 at and above 2.5 Hz.

A similar approach is followed for the LF spectra, using the LF portion of the UHRS together with a spectral shape at high frequencies dictated by the GMM and the low-frequency magnitude and distance obtained in the deaggregation (Reference 2.5.2-265). Figure 2.5.2-60R shows all 22 control motions. The control motions are provided in Table 2.5.2-33.

2.5.2.5.5.3 Horizontal Amplification Factors

Replace ESPA SSAR Section 2.5.2.5.5.3 with the following:

Site response analyses (SRA) were performed to calculate the site amplification functions associated with the PBSRS, PBIRS, and FIRS control points (Reference 2.5.2-265). The PBSRS control point is at the ground surface at elevation of 814.5 ft (248 m). The PBIRS control point is at the top of the rock, 37.5 ft below the surface at elevation of 777 ft (235 m). The FIRS control point is 115 ft (35 m) below the surface at elevation of 699.5 ft (204 m).

Note that for the PBSRS control point at ground surface, site amplification calculations were performed consistent with a geologic outcrop analysis for a free surface condition according to ISG-017(Reference 2.5.2-257). For other PBIRS and FIRS control points that are below the ground surface, since the corresponding structures will be modeled and analyzed as embedded structures, the site amplification calculations were performed consistent with a full column outcrop analysis according to ISG-017. Therefore, for control points other than ground surface, the derived PBIRS and FIRS will be a full-column outcrop ground motion which includes the full effect of the soil above the control points. The full-column outcrop includes the effects of down-going waves from soils above the elevation of the outcrop (ISG-017).

Site amplification functions (SAFs) were calculated for each combination of input control motion, randomized profile, and each of the three material models discussed in Section 2.5.2.5.3 for

each of the base-case, lower-range, and upper-range profiles and PBSRS, PBIRS, and FIRS control points. Figure 2.5.2-61R through Figure 2.5.2-69R show the amplified response spectra and amplification factors for the 60 randomized profiles associated with base-case, lower-range, and upper-range profiles and for the input control motions associated with AFEs of 10^{-3}, 10^{-4}, 10^{-5}, and 10^{-6}. These figures show the results for material model 1.

SAFs from the three material models were combined with equal weights to develop the compound SAFs for each of the base-case, lower-range, and upper-range profiles.

Figure 2.5.2-70R through Figure 2.5.2-78R show the SAFs for the 11 input control motions inputs and for each of the base-case, lower-range, and upper-range profiles and PBSRS, PBIRS, and FIRS control points. In these figures, the median SAFs are shown on left and the standard deviation of SAFs (in natural log units) are shown in right. These figures illustrate the effect of non-linearity in the response, particularly for the soil sites. The increased damping reduces the SAF at high frequencies. The decreased stiffness reduces the fundamental period and amplitude of the resonant peak.

Figure 2.5.2-79R compares the SAFs for the PBSRS, PBIRS, and FIRS control points for the input control motions associated with AFEs of 10^{-3}, 10^{-4}, and 10^{-5}.

Results of the SRA are post-processed to obtain amplitude-dependent SAFs for use in subsequent calculations (Reference 2.5.2-265). Three sets of SAFs are defined – one each for the base-case, lower-range, and upper-range profiles that characterize epistemic uncertainty in the SRA weighted 0.4, 0.3, and 0.3, respectively. The SAFs were developed separately for PBSRS, PBIRS, and FIRS control points. The SAF and its logarithmic standard deviation depend on both input rock amplitude and spectral frequency. Following the SPID (Reference 2.5.2-209), median amplification factors are not allowed to be lower than 0.5.

Figure 2.5.2-80R shows mean effective strain among all randomized profiles versus depth resulting from HF and LF input control motions associated with AFEs of 10^{-3}, 10^{-4}, and 10^{-5} considering the best-estimate velocity profile and material models 1 (left), 2 (center) and 3 (right) in the top 200 ft. Input control motion AFEs of 10^{-3}, 10^{-4}, and 10^{-5} were selected for these figures since they mainly are used to derive the PBSRS, PBIRS, and FIRS.

It is clear from this figure that higher strains are concentrated in the softer material near the ground surface, so Figure 2.5.2-78R focuses on the top 200 ft (61 m) of the profile. It is generally accepted that equivalent-linear approaches to SRA are accurate for effective strains up to a range of 0.1% to 0.4% (e.g., Reference 2.5.2-258). For the selected input control motions, the strain levels are generally within the 0.1% to 0.4% range with larger values for AFE of 10^{-5} in a limited depth range centered around 30 ft.

2.5.2.5.6 Development of V/H Ratios

Replace ESPA SSAR Section 2.5.2.5.6 with the following:

Vertical design spectra were calculated following the procedure in AECOM (Reference 2.5.2-251), with the exception of using Pezeshk *et al*. (2022) V/H model (Reference 2.5.2-259) in place of NUREG/CR-6728 (Reference 2.5.2-132). This recent model for V/H response spectral ratios was based on a comprehensive regression analysis of the NGA-East (Reference 2.5.2-181) database. The database included recordings from four earthquakes with magnitude greater than **M** 5.5. They are the 1988 **M** 5.9 Saguenay earthquake with 14 recordings; the 1985 **M** 6.8 Nahanni earthquake with three recordings; the 2011 **M** 5.7 Mineral, Virginia, earthquake with 134 recordings and the 2011 **M** 5.7 Sparks earthquake with 201 recordings (Reference 2.5.2-259). The magnitudes used for the V/H ratio range from **M** 5.9 to 6.0 at close distances of 8 to 15 km, associated with the deaggregated magnitude and distances for PGA at AEFs of 1E-4 and 1E-5.

The methodology implemented to develop the vertical ground motions follows closely that used to develop fully probabilistic site-specific horizontal motions (Reference 2.5.2-265). For application to the development of site-specific vertical hazard, the same fully probabilistic approach was used with V/H ratios (median and uncertainty estimates) substituted for horizontal amplification factors. In this case, the distributions of V/H ratios were applied to the site-specific horizontal hazard curves. As with the development of the site-specific horizontal hazard, epistemic, uncertainty in median V/H ratios was incorporated in this case by including σ_{μ}, uncertainty about the median V/H ratio.

Since V/H ratios for site conditions similar to the conditions at CRNS are not well constrained due to a lack of recordings at design magnitudes and distances, epistemic uncertainty (σ_{μ}) was accommodated in the Approach 3 analyses. Epistemic uncertainty in V/H ratios was assessed by examining the range in available models for V/H ratios appropriate for firm to hard rock site conditions (Reference 2.5.2-138). The models considered include Bozorgnia and Campbell (Reference 2.5.2-151), Bommer *et al*. (Reference 2.5.2-152), Edwards *et al*. (Reference 2.5.2-153), and Gülerce and Abrahamson (Reference 2.5.2-137), with the range in ratios in the models spanning a factor of 1.5 to 1.8 depending on frequency. The range was taken to reflect $2\sigma_{\mu}$ estimates with $\sigma_{\mu ln}$ taken as the average at 0.25 and used for epistemic uncertainty in the Pezeshk *et al*. (Reference 2.5.2-259) V/H ratios. In the Approach 3 analyses for the vertical component the source (magnitude), path (distance) and site (V_{S30}) dependent V/H ratios of Pezeshk *et al*. (Reference 2.5.2-259) along with $\sigma_{\mu ln} = 0.25$ were implemented with the site-specific horizontal hazard curves at the AFEs necessary to compute design spectra.

Additional aleatory variability about the V/H ratio, results in increased aleatory variability for the vertical component compared to the horizontal component, hence some attention is required as the contribution of site-specific aleatory variability to the hazard has already been accommodated in developing the site-specific horizontal component hazard. The site component of aleatory variability was included in developing the hard rock hazard in the variability about the hard rock ground motion prediction models. Additionally, in the Approach 3 analyses to develop the

site-specific horizontal hazard, the variability about the median amplification factors, treated as aleatory variability, was included as well. As a result, there is some double-counting of site aleatory variability, which is commonly acceptable practice. However, in the application of Approach 3 in developing the vertical hazard, care must be exercised in contributing additional unnecessary aleatory variability in the vertical component, with the implication that vertical motions reflect higher variability than horizontal motions.

The development of NGA-West2 vertical GMMs (Reference 2.5.2-154) using the same suite of recordings as in the development of the horizontal ground motion models permits a straightforward assessment of the relative degrees of aleatory variability between horizontal and vertical components for this dataset. This comparison indicates that estimates of aleatory variability in the vertical GMMs are comparable to the corresponding horizontal GMMs, suggesting that adequate aleatory variability for the vertical component has been accommodated in developing the horizontal hazard. As a result, only epistemic uncertainty in V/H ratios was incorporated in developing the vertical hazard (Reference 2.5.2-265).

2.5.2.5.7 Site-Specific Horizontal and Vertical UHRS

Replace ESPA SSAR Section 2.5.2.5.7 with the following:

Control point hazard is calculated using as Approach 3 per the SPID (Reference 2.5.2-209). That procedure computes a site-specific soil hazard curve for the spectral acceleration at a selected spectral frequency (or period) given the site-specific hazard curve for the hard rock spectral acceleration at the same oscillator period and site-specific estimates of soil/soft rock response (median and standard deviation of the site amplification functions). Approach 3 is implemented in a sequential manner, in which the hard rock hazard curve (typically only mean rock hazard) is convolved with the amplitude-dependent mean and standard deviation of site amplification.

In this project, Approach 3 is used to convolve the site amplification functions calculated for base-case, lower-range, and upper-range profiles with the rock hazard curves separately. The computed hazard curves for each profile are combined to calculate the weighted average hazard curves using the weight of 0.4 for base-case and 0.3 for lower-range, and upper-range profiles.

Mean hazard curves at the control points were calculated for the 23 spectral periods used to calculate the rock hazard (Reference 2.5.2-265). The computed hazard curves are given in tabular form in Table 2.5.2-34 through Table 2.5.2-36 for PBSRS, PBIRS, and FIRS control points (CPs). Mean hazard curves at 10 Hz, and 1.0 Hz are shown in Figure 2.5.2-81R through Figure 2.5.2-86R for PBSRS, PBIRS, and FIRS control points.

Mean UHRS for each control point are developed by interpolating the control point hazard curves at AFEs of 10^{-4}, 10^{-5}, and 10^{-6} (Reference 2.5.2-265). Rock and control point (CP) UHRS at AFEs of 10^{-4}, 10^{-5}, and 10^{-6} are shown in Figure 2.5.2-87R through Figure 2.5.2-89R for PBSRS, PBIRS, and FIRS control points and given in tabular form in Table 2.5.2-37.

Analogously, the horizontal site-specific hazard curves themselves were convolved with the suite of median V/H factors discussed in Subsection 2.5.2.5.6 to derive the corresponding vertical

site-specific hazard curves (Reference 2.5.2-265). Mean horizontal and vertical UHS at AFEs of 10^{-4}, 10^{-5}, and 10^{-6} are shown in Figure 2.5.2-90R through Figure 2.5.2-92R for PBSRS, PBIRS, and FIRS control points. Vertical UHS at AFEs of 10^{-4}, 10^{-5}, and 10^{-6} are provided in tabular form in Table 2.5.2-38.

2.5.2.5.8 Site-Specific Ground Motion Response Spectra

Replace ESPA SSAR Section 2.5.2.5.8 with the following:

The five-percent damped horizontal site-specific FIRS, PBIRS, and PBSRS are obtained by scaling the site-specific mean UHRS by appropriate design factors (DF) as detailed in RG 1.208. This approach is consistent with the performance-based approach specified in ASCE/SEI 43-19.

According to RG 1.208, the horizontal site-specific, performance-based spectra are obtained by scaling the site-specific mean UHRS by a design factor (DF):

$$Response\ Spectra\ =\ UHRS \times DF \qquad \text{Equation 2.5.2-14}$$

where UHRS is the mean 10^{-4} UHRS by incorporating the amplification factors from the SRA and the design factor is computed as below:

$$DF\ =\ max\{1.0\ ,\ 0.6(A_R)^{0.8}\} \qquad \text{Equation 2.5.2-15}$$

where A_R is the ground motion slope ratio of spectral acceleration, frequency by frequency, from a seismic hazard curve corresponding to a ten-fold reduction in hazard exceedance frequency and is computed as below:

$$A_R\ =\ (mean 10^{-5} UHRS)/(mean 10^{-4} UHRS) \qquad \text{Equation 2.5.2-16}$$

This assumes that the hazard curves are approximated by a power law equation (i.e., linear on a log-log plot) in the range of 10^{-4} to 10^{-5}. If A_R is greater than 4.2, then this assumption is not valid. In such a case, it is acceptable to use a value equal to 45 percent of the mean 10^{-5} UHRS.

FIRS, PBIRS, and PBSRS were calculated using the UHRS and Equations 2.5.2-14 to 2.5.2-16 given above. In Subsection 2.5.2.4.3.2, UHRS were calculated at the 23 spectral frequencies used in the PSHA (Reference 2.5.2-265). To capture the characteristics of site amplification at spectral frequencies other than the 23 at which the PSHA is performed, mean amplified spectral shapes are used to interpolate the UHRS to 158 spectral frequencies between 0.1 and 100 Hz. These shapes are available for each control point and profile. It is assumed that the mean amplified shape resulting from the 10^{-xx} input control motion is appropriate for interpolating the 10^{-xx} control point UHRS (where xx is -4 or -5). Furthermore, the shape resulting from the low-frequency (LF) 10^{-xx} input control motion is used to interpolate the UHRS at and below 2.5 Hz, and the shape resulting from the high-frequency (HF) input control motion is used to interpolate the UHRS above 2.5 Hz.

The computed horizontal FIRS, PBIRS, and PBSRS are shown in Figure 2.5.2-93R. The computed horizontal FIRS, PBIRS, and PBSRS are given in tabular form in Table 2.5.2-39.

Figure 2.5.2-94R illustrates the V/H ratios used in the calculations and they are tabulated in Table 2.5.2-40. Figure 2.5.2-95R shows the resulting vertical PBSRS, PBIRS, and FIRS along with the corresponding horizontal spectra (Table 2.5.2-41).

Add new Section 2.5.2.5.9:

2.5.2.5.9 Hazard-Consistent Strain-Compatible Properties

Hazard-consistent strain-compatible properties (HCSCPs) are developed for V_S, V_P, and damping for shear- and compression-waves (D_S and D_P) for hazard levels corresponding to the PBSRS and FIRS consistent with the methodology recommended by the SPID (Reference 2.5.2-209). Distributions of strain-compatible property values are obtained from the base-case, lower-range, and upper-range profile site response analyses performed in Section 5 in the same manner as site amplification functions (Reference 2.5.2-265). The distribution of each property, $f(SCP|S_a^R)$, is conditional on input rock spectral acceleration (S_a^R) and assumed to be lognormal. Consistent with the SPID (Reference 2.5.2-209), these distributions are developed for spectral frequencies of 1 Hz and PGA. HCSCPs are derived for each spectral frequency (1 Hz and PGA) and profile depth increment using

$$HCSCP\left(S_a^S\right) = \iint f(SCP|S_a^R)\ f\left(S_a^R\middle|S_a^S\right)\ d_{SCP}d_{S_a^R} \qquad \text{Equation 2.5.2-17}$$

where:

S_a^S is the hazard-consistent soil spectral acceleration for each spectral frequency (1 Hz and PGA) from the calculations above, and

$f\left(S_a^R\middle|S_a^S\right)$ is the distribution of rock spectral acceleration given soil spectral acceleration.

$f\left(S_a^R\middle|S_a^S\right)$ is the inverse conditional relationship of the site amplification functions described above and can be obtained from those results using probability theory.

The moments of the distribution for each HCSCP yield mean values and standard deviations. HCSCPs are assumed to be lognormally distributed, so medians and log standard deviations are obtained directly from the mean and standard deviation. The distributions obtained for 1 Hz and PGA are each calculated using the soil spectral amplitude corresponding to the appropriate FIRS ordinate. These two distributions are compared and combined according to the SPID (EPRI,

---

2013b) into a single distribution for each property and depth increment. Three soil profiles are derived from the resulting distribution: the best-estimate (BE) profile corresponding to the median value of each property at each depth increment; the lower-bound (LB) profile corresponding to -1 log standard deviation, and the upper-bound (UB) profile corresponding to +1 log standard deviation. The variation in shear modulus (G) represented by the LB and UB profiles is checked to ensure it covers at least BE/(1+COV) to BE*(1+COV) at each depth increment according to ISG-017. A minimum COV value of 0.5, corresponding to a "well-investigated" site per SRP 3.7.2, is used for this project. An upper V_S limit of 11,000 ft/s (3,352 m/sec) is also applied (this limit in some cases overrides the UB value of V_S implied by the minimum range of G just described).

Note that V_P and G are both calculated directly from V_S. Poisson's ratio is needed to obtain V_P and unit weight is needed to obtain G. Poisson's ratios of ratios of 0.48 for the saturated fill and soil, 0.4 for the gravel, and 0.32 for the weathered and unweathered rock were used (Reference 2.5.2-246). For this analysis it is assumed the water table elevation is at the ground surface. Unit weights are given in Section 2.5.2.5.1.2. Also note that V_P is calculated from low-strain values of V_S, while G is obtained from strain-compatible V_S. D_P was set equal to half of D_S for soil-structure interaction analysis.

A minimum value of 5,000 ft/sec (152 m/sec) is used for saturated V_P values calculated from low-strain V_S values.

A final constraint on each set of V_P values is that they do not result in a Poisson's ratio greater than 0.48 when calculated from strain-compatible V_S. This constraint is applied to avoid numerical issues common in SSI software. Some resulting V_P values may therefore fall below 5,000 ft/sec (152 m/sec).

BE, LB, and UB HCSCPs for V_S, V_P, D_S and D_P are shown versus depth in Figure 2.5.2-96R through Figure 2.5.2-99R for FIRS and PBSRS.

For SSI analysis, UB damping should be paired with LB velocities at each depth increment, and vice versa. As required by SPID (Reference 2.5.2-209), HCSCPs are derived using a probabilistic approach which maintain the hard rock annual probability of exceedances. The distribution of strain-compatible properties obtained during development of the SAFs are used to incorporate the variability in the site-specific dynamic material properties.

Add new Section 2.5.2.5.10:

2.5.2.5.10 FIRS After ISG-017 Check

The ISG-017 check was performed which ensures the adequacy of the FIRS as required by ISG-017 (Reference 2.5.2-257) before conducting the soil-structure interaction (SSI) analysis. Amongst the two available options that ISG-017 provides, option one was followed. This method ensures that the performance-based surface response spectra (PBSRS) are enveloped by the

FIRS, which were propagated to the surface using the hazard-consistent strain-compatible properties (HCSCP) calculated in Subsection 2.5.2.5.9.

To check the adequacy of the FIRS, first the Fourier amplitude spectra (FAS) is derived from the response spectral values using inverse random vibration theory (RVT). Next, the FIRS-compatible FAS was propagated from the associated elevation toward the surface using the three deterministic hazard-consistent strain-compatible profiles (BE, LB, and UB) generated in Subsection 2.5.2.5.9. Thus, the corresponding surface response spectra (SRS) at the surface were generated. Then the envelope of the SRS from the BE, LB, and UB profiles is checked to see that it enveloped the corresponding PBSRS. This evaluation was performed for horizontal and vertical FIRS/PBSRS (Reference 2.5.2-265). The SRS for the BE, LB, and UB profiles along with their envelope and PBSRS are shown in Figure 2.5.2-100R and Figure 2.5.2-101R.

If the SRS envelope fell below the PBSRS in certain frequency ranges, the FIRS was scaled higher in those frequencies and repeated the convolution until the modified FIRS convolved up to the surface enveloped the PBSRS (Reference 2.5.2-265). The final scale factors for horizontal and vertical FIRS are shown in Figure 2.5.2-102R. Figure 2.5.2-103R and Figure 2.5.2-104R show PBSRS and the SRS for the BE, LB, and UB profiles along with their envelope using the modified FIRS. The updated horizontal and vertical FIRS after ISG-017 check are given in Table 2.5.2-42.

2.5.2.6 2D Sensitivity Analysis

Replace the first paragraph of ESPA SSAR Section 2.5.2.6 with the following:

In the development of the site amplification factors, a 1D equivalent-linear site response approach was used. Potential 2D effects, due to the same geologic unit and associated velocity occurring at different depths across the site as well as broad-band amplification (basin edge) effects resulting from dipping impedance contrasts, were initially addressed by evaluating the epistemic uncertainty in V_S beneath the CRN Site. In the CRN Site ESPA (Reference 2.5.2-196) a series of 2D sensitivity analyses were performed to evaluate the potential 2D effects on earthquake ground motions due to the dipping nature of the underlying stratigraphy beneath the CRN Site (approximately 33 degrees) (Figure 2.5.4-12). The 2D model was developed by considering both Locations A and B in the power block (cited in the ESPA). Since the new proposed layout of Unit 1 with the selected SMR technology at the CRN Site is located in the vicinity of Location A, it is considered that the results of the sensitivity analysis presented in the CRN Site ESPA is applicable to the new proposed layout. In summary, the results of the 2D sensitivity analysis show that the ratio of the 2D to 1D response spectra remains below 1 (Figure 2.5.2-129) for Location A, as specified in the CRN Site ESPA; therefore, the conservative bounding design spectra developed in Subsection 2.5.2.5 should be bounding any potential 2D effects due to the dipping subsurface stratigraphy at the CRN Site. The rest of this subsection describes the development of the 2D sensitivity analysis, and results as presented in the CRN Site ESPA.

(a) Local time; corresponding UTC hour should be “10”

Notes:

TID	Unique identification number assigned in the project to each earthquake. These values are not necessarily sequential. Sequential numbering of earthquakes in uniform magnitude catalog is provided by the EQNO field.
Year, Month, Day	Date of Earthquake
Hour, Minute, Second	Time of Earthquake. The times are assumed to be UTC times. During assembly of the catalog, UTC time was selected when it was clear that other times were present among the various catalog sources. However, the reported times are based primarily on those reported in the source catalog and no attempt was made to verify that the time was UTC for the individual sources. The master catalog database contains all of the individual catalog entries with their individual times.
Lat., Long.	Location of Earthquake (degrees). The precision of the reported location represents the precision reported for the preferred entry among the source catalogs. Variability in the precision in location among the earthquake entries is not an issue as the earthquake recurrence rates are computed using grid sizes of ¼ or ½ degree longitude and latitude.
Depth	Earthquake Depth (km) or Depth of Focus; 0 indicates no measured or estimated depth.
ERH	Estimated Horizontal Location Uncertainty (km). This entry provides a measure of the uncertainty in location of the earthquake. The values represent a mixture of reported standard errors in location of instrumentally located earthquakes from various catalog sources and estimates of location uncertainty for locations based on felt effects (shaking intensity). Note: ERH does not appear to be used in specific analyses presented in the CEUS SSC Report, so this parameter was not estimated in the update of the earthquake catalog. Dashes indicate no data.
E[**M**]	Expected value of moment magnitude.
N*	Equivalent earthquake count. This value is used to account for the effects of magnitude uncertainty in computing unbiased earthquake recurrence parameters.
sig**M**	Standard deviation in the estimated moment magnitude, E[**M**]. It is used to compute N*
EQNO	Earthquake number in the uniform moment magnitude CEUS SSC Project catalog.
Flag	Flag for dependent earthquakes, where a value of 0 indicates an independent earthquake and a value greater than 0 indicates a dependent earthquake with the value of flag indicating the EQNO of the mainshock of the cluster.
Dist	Epicentral distance (from epicenter to project site) in kilometers.
CEUS SSC	Central and Eastern United States Seismic Source Characterization for Nuclear Facilities

Replace Table 2.5.2-16 through Table 2.5.2-32 with the following:

Table 2.5.2-16R Summary of Source Parameters in the Revised Charleston RLME Source

Zone	Boundary Type	Sense of Slip	Rupture Strike	Rupture Dip	Recurrence Model
1886 Rupture (0.3)*	Leaky (1.0)	Reverse (1.0)	S0–15°W uniformly distributed (1.0)	40–50°W uniformly distributed (1.0)	Poisson (0.5) Renewal (0.5)
Local (0.5)	Leaky (1.0)	Reverse (0.5)	N-S (0.6)	30–60° random both directions (1.0)**	Poisson (0.9) Renewal (0.1)
			N45°E (0.2)		
			E-W (0.1)		
			N45°W (0.1)		
		Strike-slip (0.5)	N-S (0.3)	75–90° random both directions (1.0)**	
			N45°E (0.5)		
			E-W (0.1)		
			N45°W (0.1)		
Regional (0.2)	Strict (1.0)	Reverse (0.5)	N-S (0.6)	30–60° random both directions (1.0)**	Poisson (1.0)
			N45°E (0.2)

Table 2.5.2-18R Mean Magnitude (M), Distance (R), and Durations for Low Frequency and High Frequency Response Spectra for Eleven Mean Annual Frequency of Exceedances

Frequency range	Value	1.00E-02	4.00E-03	2.00E-03	1.00E-03	4.00E-04	1.00E-04	4.00E-05	1.00E-05	4.00E-06	1.00E-06	2.00E-07
HF	M	6.1	6.2	6.2	6.1	6.0	6.0	6.1	6.2	6.3	6.4	6.5
	R (km)	218.4	183.5	151.5	113.3	66.4	25.9	15.8	9.7	8.0	6.5	5.7
	Dur(sec)	21	18	14	11	9.0	6.5	6.5	6.5	6.5	6.5	6.5
LF	M	6.7*	7.1*	7.3*	7.4*	7.5*	7.6*	7.6*	7.7*	7.7*	6.7	6.8
	R (km)	388.4*	408.9*	418.8*	424.3*	426.3*	423.1*	418.2*	408.5*	399.7*	21.8	12.3
	Dur(sec)	42	48	51	54	56	57	57	56	56	9.0	8.6

Notes:

HF = High Frequency = 5 to 10 Hz (per RG 1.208)

LF = Low Frequency = 1 to 2.5 Hz (per RG 1.208)

M = Magnitude

R = Distance

*M and R calculated for R>100km per RG 1.208 because the contribution to hazard for R>100 km is more than 5% of the total hazard.

2.5.3 Surface Deformation

Replace the second paragraph of ESPA SSAR Section 2.5.3 with the following:

RG 1.208 states, “Comprehensive geological, seismological, geophysical, and geotechnical engineering investigations should be performed.” It also states that these investigations should be performed at four levels with the degree of detail based on distance from the site.

2.5.3.1 Geological, Seismological, and Geophysical Investigations

Insert the following after the last bullet of ESPA SSAR Section 2.5.3.1:

- Information on the August 9th, 2020, Sparta earthquake including the Department of Energy Y-12 Probabilistic Seismic Hazard Analysis (PSHA) from 2021 (Reference 2.5.3-19).

2.5.3.1.2 Regional and Local Geologic Studies

Replace the last sentence of ESPA SSAR Section 2.5.3.1.2 with the following:

More recent research has been published describing possible paleoseismic evidence for large magnitude ETSZ paleoearthquakes near Douglas Reservoir, approximately 50 mi (80 km) east of the CRN Site (References 2.5.3-12, 2.5.3-13, and 2.5.3-14). Hatcher et al. (Reference 2.5.3-12) describe possible evidence of multiple paleoearthquakes from paleoseismic trenches and geologic mapping (faults, fluidization structures, bleached or clay-filled fractures, and sand dikes), suggesting the most-recent event may have occurred sometime after approximately 73 ka. Warrell et al. (Reference 2.5.3-13) provides additional information on possible paleoseismic features at Douglas Reservoir. Description of these features is presented in Subsection 2.5.3.2.6.

Cox et al. (Reference 2.5.3-20 and Reference 2.5.3-92) describe evidence for surface faulting with ≥6 ft (2 m) of throw exposed in an alluvial terrace along the Little Tennessee River near Vonore, Tennessee. The age of the terrace is not well constrained, and Cox et al. (Reference 2.5.3-20) do not report evidence for multiple events at this site.

In another abstract, Glasbrenner et al. (Reference 2.5.3-35) describe geologic mapping and paleoseismic trenching along the Tellico Reservoir about 22 mi (34 km) southeast of the CRN Site. Based on limited geologic field observations and an apparent seismicity alignment, Cox et al. (Reference 2.5.3-72), Warrell et al. (Reference 2.5.3-73), and Cox et al. (Reference 2.5.3-92) propose an active, 70 mi (110-km)-long “Quaternary faulting corridor” (referred to as the Dandridge-Vonore fault zone; DVFZ) in the ETSZ. They suggest that this fault corridor may be responsible for at least some of the paleoearthquakes interpreted from exposures near Dandridge, Alcoa, and Vonore, Tennessee. Additional details regarding the proposed DVFZ are provided in a recent field trip guidebook (Reference 2.5.3-74); and were further published in Cox et al. (Reference 2.5.3-92).

Other studies of the ETSZ that post-date development of the CEUS-SSC model have examined the deep crustal structure (Reference 2.5.3-75; Reference 2.5.3-76; Reference 2.5.3-77) and the

shallow crustal structure (Reference 2.5.3-78; Reference 2.5.3-79) of the ETSZ. Carpenter et al. (Reference 2.5.3-80) suggests that the **M** 4.2 Perry County, Kentucky, earthquake is related to the ETSZ, thus extending the zone farther north than previously recognized. Yang and Salem (Reference 2.5.3-81) used Permanent Scatterers Synthetic Aperture Radar Interferometry (PSInSAR) data to suggest that land surface deformation may be spatially associated with areas of higher seismicity rate in eastern Tennessee, but caution that many other processes besides earthquake activity can contribute to surface deformation.

A PSHA performed for the nearby Department of Energy Y-12 National Security Complex in Oak Ridge in 2021 (Reference 2.5.3-19) evaluated this new information on the ETSZ to see if it warranted changes to the CEUS-SSC model. This study developed an additional hazard sensitivity analysis to evaluate the postulated Quaternary faulting corridor associated with the Dandridge-Vonore fault zone. The results of DVFZ hazards sensitivity analysis indicate that the DVFZ, as characterized, does not significantly increase hazard at the Y-12 site (Reference 2.5.3-19). The studies further concluded that results from the ongoing paleoseismic studies in the ETSZ are preliminary and do not provide adequate evidence for defining the ages and repeat times of earthquakes and therefore do not provide adequate evidence for defining an RLME seismic source for the ETSZ, and thus no revisions to the CEUS-SSC model are required to account for more recent data from the ETSZ (Reference 2.5.3-19). See Subsection 2.5.2.2.6.1.3 for a discussion of ETSZ Maximum Magnitude (Mmax) sensitivity studies.

2.5.3.4 Ages of Most Recent Deformation

2.5.3.4.1 Bedrock Faults

Insert the following after the last paragraph of ESPA SSAR Section 2.5.3.4.1:

Within the Site Region, however, there is a recently identified fault related surface rupture attributed to the Mw 5.1 August 9, 2020, Sparta, North Carolina earthquake about 188 mi (302 km) ENE of the CRN Site. This is considered the first documented seismic surface rupture in the eastern United States, leading to the identification of the Little River Fault (Reference 2.5.3-82).

Although the Little River Fault produced strong ground shaking and surface rupture, the geomorphology and focal mechanism analysis of fault seismicity is suggestive of an underlying structural control (Reference 2.5.3-84; Reference 2.5.3-94) and evidence for repeated fault movements within the Quaternary have been documented (Reference 2.5.3-93; Reference 2.5.3-94), it is not considered a hazard to the Site. This is primarily because the Little River Fault only has ~2.5 mi (4 km) of documented surface rupture, which is less than the 4.3 mi (7 km) length criteria needed to be considered a seismic hazard by the U.S. Geological Survey National Seismic Hazard Model (NSHM) for the conterminous United States. For this reason, the Little River Fault is not included as a fault section in the updated 2023 National Seismic Hazard Model database (Reference 2.5.3-84).

Furthermore, the Sparta earthquake is not within the ETSZ (Figure 2.5.2-24R) and is not considered related to the same tectonics as the ETSZ, as it was a shallow event (~0.6 mi (1 km) depth) and all events in the ETSZ have deep sources (4.3-15.5 mi (7-25 km) depth) (Reference 2.5.3-95). Additionally, recent analysis of stress fields in the CEUS using geomechanically constrained stress inversions of earthquake focal mechanisms indicate that the stresses that were responsible for the Sparta earthquake are not compatible with the ETSZ stress field (Reference 2.5.3-96). The location of the Sparta earthquake therefore falls within the Paleozoic Extended Crust seismotectonic zone, in which the CRN Site also resides. The seismic event accordingly does not add any additional hazard for the Site beyond what is already accounted for in the CRN site PSHA (Subsection 2.5.2). It is speculated that any large event along the Little River Fault near Sparta, North Carolina would most likely be attenuated prior to reaching the Clinch River site, but it is unclear to what degree (Reference 2.5.3-95). The Sparta earthquake and Little River Fault are discussed in more detail in Subsection 2.5.3.7.1.

2.5.3.6 Characterization of Capable Tectonic Sources

Insert the following after the last paragraph of ESPA SSAR Section 2.5.3.6:

The recent 2020 Sparta, North Carolina earthquake occurred within the Site Region and caused surface rupture along the Little River Fault (Reference 2.5.3-82), indicating that it is a capable tectonic source (Reference 2.5.3-95). This Little River Fault is however located outside of the ETSZ, and the Sparta earthquake was determined to have a shallow hypocentral depth (<3 mi (5 km)) (Reference 2.5.3-87) and be a low-angle, NE-vergent reverse fault, indicating that it occurred in different stress field (Reference 2.5.3-96) and therefore does not fit into the characteristics of the ETSZ. The Little River Fault is therefore not considered to pose a hazard to the CRN Site like the ETSZ does (Reference 2.5.3-95). The Sparta earthquake and Little River Fault are discussed in more detail in Subsection 2.5.3.7.1.

2.5.3.7 Designation of Zones of Quaternary Deformation in the Site Region

Insert the following after the first paragraph of ESPA SSAR Section 2.5.3.7:

As of 2020, there is a newly discovered Quaternary fault in northwestern North Carolina named the Little River Fault. This Fault experienced movement, causing surface rupture during the Mw 5.1 August 9, 2020, earthquake near Sparta, North Carolina. The Sparta earthquake produced the first documented seismic surface rupture in the eastern United States allowing identification of the Little River Fault (Reference 2.5.3-82). The epicenter is located approximately 188 mi (302 km) ENE of the Clinch River Site, placing it within the site region.

Add new Section 2.5.3.7.1:

2.5.3.7.1 2020 Sparta Earthquake and the Little River Fault

The Little River Fault is of definite Quaternary activity having just been discovered due to its movement causing surface rupture during the August 9, 2020, Mw 5.1 Sparta earthquake, with its

epicenter located ~2 mi (~3 km) south of Sparta, North Carolina (36.488° N, 81.106° W) in northwest North Carolina (Reference 2.5.3-82), approximately 188 mi (302 km) ENE of the Clinch River Site. This earthquake occurred in the allochthonous Neoproterozoic-Ordovician Ashe and Alligator Back metamorphic suites in the Gossan Lead thrust sheet in the eastern Blue Ridge (Reference 2.5.3-85 and Reference 2.5.3-93) and shook much of the eastern United States producing the first documented surface rupture due to faulting east of the New Madrid seismic zone (Reference 2.5.3-82). The co-seismic surface rupture was initially traceable along a 1.2 mi (2 km) long zone, with offsets indicating predominantly reverse displacement with additional deformation observed south of the main surface rupture as well. High-resolution LiDAR acquired a few months after the earthquake allowed identification of approximately 2.5 mi (4 km) of surface rupture (Reference 2.5.3-93 and Reference 2.5.3-94). Although there were no casualties or significant damage to major infrastructures, damage was recorded to roads, utility lines, and masonry structures, including the collapse of walls and chimneys and the cracking and shifting of foundations (Reference 2.5.3-82).

The Sparta earthquake was the largest in North Carolina in nearly 100 years and the strongest in the eastern United States since the 2011 Mw 5.8 Mineral, Virginia, earthquake. The earthquake sequence included eight foreshocks (Mw 1.8-2.6) during the previous 24 hours before the mainshock and at least 300 aftershocks over the next six months (up to Mw 2.9) (Reference 2.5.3-82). The main shock of the seismic event had a maximum intensity of VI-VII in Sparta and generated peak ground accelerations of at least 0.2 g (Reference 2.5.3-82). According to the USGS, (Reference 2.5.3-86) an intensity of II was recorded at the CRN site area. This deformation is unique as surface ruptures by faulting are rarely reported for earthquakes with magnitude less than **M** 6.0, and it occurred in a very low strain rate intraplate setting, where earthquake surface deformation is rare (Reference 2.5.3-82).

The mainshock hypocenter and focal mechanism have been estimated independently by several groups (Figure 2.5.3-23), namely the Center for Earthquake Research and Information at the University of Memphis (CERI) (Reference 2.5.3-87), the Saint Louis University Earthquake Center (Reference 2.5.3-88) and the United States Geological Survey (Reference 2.5.3-86). While the first two entities calculated the depth of the hypocenter at 0.6 mi (1 km) or less, the USGS calculated their preferred hypocenter location to be 2.5 mi (4.1 km) (Reference 2.5.3-86 and Reference 2.5.3-82). Although all three calculations resulted in a NW-SE to WNW-ESE striking fault plane with dips between approximately 50-60° SW for the focal mechanism, the preferred USGS (Reference 2.5.3-86) orientation is 176, 48° W for the nodal plane (Reference 2.5.3-82). Figueiredo (Reference 2.5.3-94) discounts the USGS determination of hypocenter depth and nodal plane because their closest stations were approximately 30 mi (50 km) away. These orientations are all oblique to the regional NE-SW structural trend.

A local seismic monitoring network was deployed within 48 hours of the initial earthquake by CERI, and seismic monitoring of continued minor aftershocks (**M** 1-2), which were still taking place years after the mainshock, indicate that while some events occurred at approximately 3.7 mi (6 km) depth, the majority are in the 0.6-2.5 mi (1-4 km) range (Reference 2.5.3-94). Analysis of these aftershocks' seismicity has aided in refining the mainshock hypocenter depth to ~0.8 mi (1.3 km) (Reference 2.5.3-94), considerably shallower than the USGS preferred depth. A

depth of around 0.6 mi (1 km) or shallower for the mainshock is however the currently accepted hypocentral depth range (Reference 2.5.3-93 and Reference 2.5.3-94).

This faulting occurred on the previously unidentified and newly named Little River Fault due to its proximity to the Little River which runs through Sparta (Figure 2.5.3-24). The fault is determined to be a west-northwest striking (~110°), south-southwest dipping (45-60°), left lateral oblique reverse fault (Reference 2.5.3-89). The sense of motion is supported by the recorded displacement of geodetic monuments on the hanging wall and footwall. The regional maximum horizontal stress field (SHmax) is oriented NE-SW to ENE-WSW (Reference 2.5.3-90), consistent with an oblique-reverse focal mechanism and overall reverse fault characteristics on a WNW-ESE striking fault plane.

The majority of the surface rupture was initially identified to the south and southeast of Sparta, stretching for ~1.2 mi (2 km) and across a generally < 80 ft (25-m)-wide zone, but there was no major surface deformation identified near the epicenter (Reference 2.5.3-82). Evidence incudes straight, tens to hundreds of meters long, 110-120°-trending, occasionally en échelon, ground ruptures with an adjacent scarp formed by reverse motion folding and flexure of the topography, with some associated fractures/splays that vary more NW in orientation (Reference 2.5.3-93). The scarp has an average height of 8-12 in (20-30 cm) and a maximum of ~20 in (50 cm) in one anomalous location (Figure 2.5.3-25) (Reference 2.5.3-82 and Reference 2.5.3-93). Along the rupture, which has four different sections (Figure 2.5.3-24), the southern block is consistently uplifted indicating complex oblique reverse motion.

Away from the main fault trace, other co-seismic surface deformation resulting from ground shaking or translational sliding was recognized such as ground fissures in less consolidated material in road cuts and riverbanks southwest of Sparta (Reference 2.5.3-82). Features include the opening of fissures that are centimeters to decimeters in length and millimeters to centimeters wide in the Little River riverbanks and fissures extending for several meters that exhibit shortening and extensional displacement in an industrial parking lot believed to be related to deformation along several preexisting pavement discontinuities (Reference 2.5.3-82).

Subsequent LiDAR analysis of data acquired after the mainshock, and compared to 2016 LiDAR data, revealed that the surface rupture is actually approximately 2.5 mi (4 km) long (Reference 2.5.3-93 and Reference 2.5.3-94). En echelon, subparallel lineaments observed in the LiDAR extending to the northwest (believed to be unruptured in 2020 event) are suspected older segments of the Little River Fault (Figure 2.5.3-24). This data indicates that the Little River Fault length could extend to 3.7 mi (6 km) (Reference 2.5.3-93) or potentially to 7.5 mi (12 km) if all lineaments are actual expressions of the Little River Fault (Reference 2.5.3-94). Comparison of the post-rupture LiDAR data with older LiDAR data (2016) indicates left lateral motion detected up to 1.2 mi (2 km) from rupture and vertical deformation up to 330 ft (100 m) away. However, 2016 data could have other factors influencing the overall differences (e.g. a location of surface lowering is related to erosion) (Reference 2.5.3-94).

Detailed geologic mapping reveals individual fault strands occur in an en-echelon pattern within a 39 ft- (12 m-) wide zone and has identified several strands of brittle faults oriented similar to the co-seismic rupture and fault that are characterized by deformation zones 0.4-10 in (1 to 25 cm) wide, often with several brittle faults localized within several meters in outcrops

(Reference 2.5.3-93). The Paleozoic foliation in the bedrock can be seen fractured and rotated into the fault, with microbreccia and manganese-coated slickenside clay seams present along some fault fractures with variable orientations in saprolitic bedrock exposed adjacent to the Little River Fault (Figure 2.5.3-25). Soft-sediment deformation in alluvium has also been documented at multiple locations along river and stream banks along sections of other NW-trending lineaments (Reference 2.5.3-93). Cosmogenic radionuclide analysis of gravel in colluvium overlying one of the fault strands in the saprolite has given depositional ages of 500 ka, indicating that faulting occurred along the fault zone during the Pleistocene (Reference 2.5.3-93). These observations highly suggest paleoseismicity and reactivation of the Little River Fault through at least Quaternary time.

Four trenches (two initial small excavations and two subsequent traditional paleoseismic trenches) excavated across the surface rupture reveal that this earthquake propagated to the surface along a preexisting structure in the shallow bedrock, which had not been previously identified as an active fault. Additionally, ground-penetration radar and electrical tomography resistivity profiles were acquired normal to the rupture trace, imaging a m-wide south-dipping fault zone (Reference 2.5.3-97). Features in the initial small excavations include a low-angle thrust fault in one trench with ~4 in (10 cm) of fault slip in surficial fill deposits causing 1.5 in (4 cm) of vertical displacement which roots into a steeper preexisting plane (N 115°,S 45°) in underlying weathered bedrock, interpreted to be associated with the Paleozoic fabric (Reference 2.5.3-82). Both dip-slip and oblique slickenlines were identified in the low-angle and steeper fault surfaces (Reference 2.5.3-89). Older fault gouge with manganese-coated surfaces and breccia were observed in the weathered bedrock indicating brittle deformation attributed to previous movement (of unknow age, but probably Cenozoic) along the Little River Fault (Reference 2.5.3-82).

The later traditional paleoseismic trenches revealed a complex fault zone ~50 ft (15 m) wide, with multiple WNW-ESE to NW-SE strands where a low grade metamorphosed greywacke is thrusting amphibolite (Reference 2.5.3-97). They also show that the movement during 2020 Sparta earthquake was accommodated by at least two separate fault splays striking ~110° and dipping 45-60° SSW that offset both bedrock and overlying middle to late Pleistocene soil and colluvium (Reference 2.5.3-94). While one of the fault splays was responsible for the surface rupture, the other splay fault did not rupture the surface but did have movement during the 2020 event (Reference 2.5.3-94).

Based on observations in the trenches as well as electrical resistivity tomography data, the deformation zone along the fault ranges between 33-66 ft (10-20 m) and overall vertical displacement is a combined 20 in (50 cm) including surface and subsurface (Reference 2.5.3-94). At least three separate seismic events on the two fault splays in the two traditional paleoseismic trenches (about 0.6 mi (1 km) apart) were observed, indicating recurrent activity on the Little River Fault (Reference 2.5.3-94). Preliminary optically stimulated luminance (OSL) data on faulted sediments indicates the three separate events took place in the last 50 k.y. equating to about 12 in (30 cm) per event during the Holocene (Reference 2.5.3-94).

While the derived focal mechanisms, Interferometric Synthetic Aperture Radar (InSAR) data and geodetic monuments indicate oblique-reverse motion, the geologic field evidence suggests

predominantly reverse faulting and associated folding along a low-angle (~20°) fault plane that roots in a steeper preexistent fabric (~50°) (Reference 2.5.3-82). It is speculated that this discrepancy could indicate complex strain partitioning or a change of slip during the earthquake, with the initial, deep rupture having been predominantly strike-slip along a steeper structure with up-dip failures occurring on shallower preexisting planar discontinuities in the bedrock accommodating most of the reverse component (Reference 2.5.3-82).

Based on continued focal mechanism analysis of seismicity of aftershocks, it was subsequently suggested that the fault that caused surface rupture was a shallow reverse splay fault that roots into a deeper main, blind, subvertical, left lateral, strike-slip fault (Reference 2.5.3-94). The surface rupture fault, as well as the other subparallel reverse fault strands are splays off of this main fault which is oriented ~150 degrees and is believed to reach within 0.6 mi (1 km) of the surface (Reference 2.5.3-94). Total rupture length is estimated to be 2.5 mi (4 km) on reverse fault splays and 2 mi (3 km) on blind subvertical strike slip main fault for a cumulative rupture length of 4.3 mi (7 km) between the main and splay faults (Reference 2.5.3-94).

Modeling of InSAR data deformation field for the Sparta earthquake recorded by the Japan Aerospace Exploration Agency's Advanced Land Observing Satellite #2 is suggested to indicate Little River Fault surface rupture is associated rather with a very shallow normal faulting event (Reference 2.5.3-91). This is in opposition to the seismic movements indicated by Figueiredo et al. (Reference 2.5.3-82) for the Sparta earthquake surface rupture. However, Wick and Chiu (Reference 2.5.3-91) do not contest that the overall seismic motion was not reverse in movement, rather they suggest that the normal fault could be an induced secondary effect of near-surface shear failure on a pre-existing structure, like a fracture or foliation plane. They suggest that the Little River Fault rupture is an observed interaction between the seismically recorded reverse fault and the geodetically recorded normal fault. The normal fault likely progressed aseismically, perhaps induced by the seismic reverse fault with unmapped small-scale tectonic features aiding in localizing the two slip events (Reference 2.5.3-91). Other than the InSAR based argument put forth by Wicks and Chiu (Reference 2.5.3-91), there is no evidence for normal movement, and it is assumed to be inaccurate analysis (Reference 2.5.3-94).

Although the Little River Fault produced strong ground shaking and documented surface rupture, it is not included as a Quaternary fault section in the 2023 National Seismic Hazard Model database because the ~2.5 mi (4 km) long surface rupture is less than the 7 km long criteria to be included in the database. At the time of publishment of the database, however, there was not yet published evidence for recurrent Quaternary deformation along the Fault (Reference 2.5.3-84). Though not yet unequivocally documented (Reference 2.5.3-83), subsequent published abstracts (Reference 2.5.3-97) and unpublished data as discussed here (Reference 2.5.3-93 and Reference 2.5.3-94) describes evidence for repeated fault movements throughout the Quaternary, which now supports classification of the Little River Fault as a Quaternary fault section.

As discussed here, the surface rupture is located along a subtle at least 6 mi (10-km) long WNW-ESE-trending topographic lineament visible in digital elevation models and centered on the fault zone (Reference 2.5.3-82) (Figure 2.5.3-24). The Little River Fault is possibly part of a

WNW-ESE set of regional lineaments and faults inferred to have Cenozoic activity that cross the dominant NE-SW Appalachian structural grain, such as the Boone and Mills Gap Faults, located 30 mi (50 km) and 93 mi (150 km) to the southwest, respectively, to which it is subparallel (Reference 2.5.3-83). Other E-W trending lineaments in North Carolina such as the Mesozoic Swannanoa and Laurel Creek lineaments exist that have no known modern seismicity, but there has been no analysis of paleoseismicity along those features that has been found in the literature (Reference 2.5.3-95).

The Sparta earthquake, along with the 2011 Mw 5.8 Mineral, Virginia earthquake, both occurred along structures not included in any database as potentially active, suggesting that the regional seismic hazard may be underestimated in the Eastern United States (Reference 2.5.3-82). However, since the Sparta earthquake is not within the ETSZ (Figure 2.5.2-24R) and therefore falls within the Paleozoic Extended Crust seismotectonic zone, in which the CRN Site also resides, the seismic event does not add any additional hazard for the Site beyond what is already accounted for in the CRN site PSHA (Subsection 2.5.2).

2.5.4 Stability of Subsurface Materials and Foundations

Replace the third paragraph of ESPA SSAR Section 2.5.4 with the following:

Supplemental site-specific field exploration (2023 CRN Site investigation) and testing were planned and conducted to supplement the existing site characterization data for the selected GEH BWRX-300 reactor technology. The purpose of the additional testing and exploration program is to ensure that the site-specific safety requirements were met, and potential hazards are identified and addressed before construction begins. The raw data from the 2023 CRN Site investigation program are presented in Reference 2.5.4-66 and Reference 2.5.4-67 or are pending further processing and analyses. These results provide additional data to supplement the existing datasets (from the ESPA) to inform any necessary modifications to the design (if necessary) at the later stages of the project.

2.5.4.1 Geologic Features

Replace ESPA SSAR Section 2.5.4.1 with the following:

The following discussions focus on geologic features at the CRN Site. More detailed descriptions of geologic features are presented in Subsection 2.5.1. The information is taken from the 2013 CRN SMR investigation program (outlined in Subsection 2.5.4.3) and the 2023 BWRX-300 SMR supplementary investigation. For reference, the existing site elevations range from approximately 855 (MP-406) to 780 feet (ft) (MP-207, MP-211) with an average elevation of about 810 ft for the CRN Site, and around 800 ft for the Unit 1 location. A finished plant grade elevation of 814.5 ft North American Vertical Datum of 1988 (NAVD88) is expected as the final plant grade elevation. Foundation embedment for the vertical shaft of the Reactor Building (RB) is at a depth of 115 ft (699.5 ft) below finished grade.

All references to elevation given in the following subsections are to NAVD88, with the exception of elevations pertaining to the CRBRP which are with respect to the National Geodetic Vertical Datum of 1929 (NGVD29). In the project area, there is generally a difference of less than 0.5 ft between NAVD88 and NGVD29, with NGVD29 being greater. Likewise, all exploratory point locations are provided relative to Tennessee State Plane Coordinates in North American Datum of 1983 (NAD83) and all references to depth are below the existing ground surface unless stated otherwise.

2.5.4.1.3.1 Discontinuities

Replace the first sentence of the second paragraph of ESPA SSAR Section 2.5.4.1.3.1 with the following:

ATV data collected during the 2013 CRN Site subsurface investigation (Appendix C, Reference 2.5.4-1) indicates that the highest frequency of joints occurs in the upper 100 ft of bedrock.

Insert the following after the third paragraph of ESPA SSAR Section 2.5.4.1.3.1

The supplemental site-specific field exploration (2023 supplementary investigation) and testing have been performed with considerations on the selected BWRX-300 SMR reactor technology. One of the objectives of the additional testing and exploration program was to inform the description of the discontinuities surrounding the vertical shaft of the Reactor Building (RB).

The 2023 supplementary investigation ATV data are broadly consistent with that of the 2013 data, though with a much smaller dataset due to the lesser number of ATV data collected. The strike of the 2023 fractures ranges predominantly between 220- and 250-degrees azimuth with a mean of 234.4 degrees, while the dips predominantly range between 310- and 340-degrees azimuth with a mean of 324.4 degrees. The two dominant sets in the 2023 fracture data are consistent with the dominant sets in the 2013 dataset in that both are oriented parallel to strike. While the most dominant set is most consistent (mean orientation of 234/56), the subordinate set dips SE, close to bedding orientation, but has overall a steeper average dip and slightly rotated strike (mean orientation of 075/54) than the secondary set in the 2013 data. Greater details of the 2023 BWRX-300 SMR subsurface investigation fracture sets and comparison to early investigation data are discussed in Reference 2.5.4-66.

2.5.4.1.3.2 Shear-Fracture Zones

Replace the first sentence of the first paragraph of ESPA SSAR Section 2.5.4.1.3.2 with the following:

A detailed discussion on the shear-fracture zones encountered in the 100- and 200-series borings (from the 2013 investigation at Locations A and B, respectively) at the CRN Site is provided in Subsections 2.5.1.2.4 and 2.5.1.2.6.4.

Replace the second paragraph of ESPA SSAR Section 2.5.4.1.3.2 with the following:

According to the proposed layout of Unit 1, the vertical shaft of the RB will be constructed within the Benbolt Formation. The shear-fracture zones are incorporated in the average Geological Strength Index (GSI) rating for each stratigraphic unit for rock mass characterization (Subsection 2.5.1.2.6) in order to characterize the subsurface condition at the RB location.

Characterization of the shear-fracture zones are based on the 100-, 200-, and 400-series borings drilled at the CRN Site during the 2013 CRN Site investigation. Similar healed shear-fracture zones were identified during the 2023 field investigation for the selected BWRX-300 reactor technology. They were identified and characterized in only 8 of the 16 rock core boreholes drilled. These healed shear-fractures were identified in depth intervals corresponding to the Rockdell Formation (25 intervals out of 28 described intervals), the Benbolt Formation (2 intervals) and one occurrence in the recently first-time drilled Witten Formation. The presence of these healed shear-fractures is not observed to be laterally continuous zones through multiple borings with shear-fracture zone features in the Benbolt only occurring in the upper strata of the formation, while those identified in the Rockdell Formation appear to comprise different localized zones all throughout the formation thickness. The only occurrence in the Witten Formation was described

in the bottom third of the formation. These features as identified in the 2023 subsurface investigation are discussed in more detail in Reference 2.5.1-66.

Based on the determined age of the shear-fracture zone features during Alleghenian shortening, they are not considered an active hazard to the CRN site. It is furthermore suggested that the previously established term “shear-fracture” for these features is a misnomer within the site, as they are not traditional tectonic shear zones. Regardless, they are factors in the foundation rock mass assessment for bearing capacity and further characterization of such features, if identified, shall be performed via geologic mapping during excavation for the deeply embedded RB shaft.

Delete the third paragraph of ESPA SSAR Section 2.5.4.1.3.2.

2.5.4.1.3.3 Weathered and Fracture Zones

Delete the third paragraph of ESPA SSAR Section 2.5.4.1.3.3.

2.5.4.1.4 Karst Features

Replace the second and third paragraph of ESPA SSAR Section 2.5.4.1.4 with the following:

Contrary to previous drilling investigations at the CRN Site in which many dissolution features larger than 0.1 ft were described, only two (2) of such cavity size were described in cored rock samples recovered and described in the 2023 CRN Site investigation. One cavity was described in the rocks of the Witten Formation, while the other cavity was interpreted as a 0.9 ft maximum size based on core loss within rocks of the Rockdell Formation (Reference 2.5.4-66).

A discussion on the cavities encountered in the borings drilled as part of the 2013 and 2023 CRN subsurface investigations is provided in Subsection 2.5.1.2.6. A number of cavities encountered in the Rockdell Formation (MP-424) are below the deepest foundation embedment depth (El. 699.5 ft). These (five) cavities were encountered at average cavity elevations between approximately 660 to 680 ft, and they ranged in height from 0.7 to 4.3 ft (Table 2.5.1-11R).

Additionally, a three dimensional FE model was developed to evaluate the impact of potentially un-detected karstic cavities within the Benbolt formation, where BWRX-300 Unit 1 RB will be located. The selection of the size and location of the karst cavities and disturbed rock mass zone was in part informed by the ESPA SSAR Subsection 2.5.4 (Reference 2.5.4-64). It is noted that in order to simulate the actual condition at the CRN Site, the size of the cavities in those models were compatible with the height of the cavities detected and observed in the 2013 CRN site investigation program. Consistent with ESPA cavity evaluation, two spherical karst cavities were considered to represent the worst-case scenario for the stability of the BWRX-300 RB deeply embedded vertical shaft and surrounding structures: a 15-ft (diameter) cavity located 5 ft beneath the centerline of the RB mat foundation; and a 15-ft (diameter) cavity located 5 ft adjacent to the RB vertical shaft and 2-ft below the top of the unweathered rock below the Radwaste Building (heaviest surface structure). The details are provided in Subsection 2.5.4.13.

A mitigation plan to address possible cavities encountered at and below the foundation levels of SC1 structures during excavation is discussed in Subsection 2.5.1.2.6.10.

2.5.4.2 Properties of Subsurface Materials

2.5.4.2.1 Description of Subsurface Materials

Replace ESPA SSAR Section 2.5.4.2.1 with the following:

The following is a brief description of the subsurface materials and their range in thickness encountered at the site. The information is taken from the borings made for the 2013 CRN subsurface investigation (outlined in Subsection 2.5.4.3.2) contained in Appendix B of Reference 2.5.4-1. Descriptions of the subsurface materials encountered in the 2023 BWRX-300 SMR subsurface investigation are discussed in Reference 2.5.4-66. The two investigations reveal similar lithologic descriptions for the subsurface materials at the CRN Site.

Table 2.5.1-2R summarizes the borings drilled and the subsurface material encountered for the 2013 CRN subsurface investigation. For reference, the existing site elevations in the areas explored range from about 762 (MP-407) to 855 ft (MP-406) (both of these borings are located outside of the power block) with an average elevation of approximately 806 ft. Finished grade elevation at the Unit 1 location will be 814.5 ft.

2.5.4.2.1.2 New Backfill

Replace ESPA SSAR Section 2.5.4.2.1.2 with the following:

New granular backfill will be used to raise grade to the final plant grade elevation (EL. 814.5 ft). This elevation increase near the vertical excavation of the RB is planned to be achieved with the conceptual design of compression rings. The details and assumptions on these elements (at the conceptual design stage) are provided in Subsection 2.5.4.13.

A description of the proposed granular backfill material is contained in Subsection 2.5.4.5.

2.5.4.2.1.3 Weathered Rock

Replace ESPA SSAR Section 2.5.4.2.1.3 with the following:

The depths and thicknesses of weathered rock encountered in the borings are summarized in Table 2.5.4-3. The 2013 CRN Site subsurface investigation shows that weathered rock is encountered in most of the borings drilled at the site (Appendix B.1, Reference 2.5.4-1). During the 2013 drilling operations, weathered rock was defined as a material having a SPT of 50 blow counts resulting in less than 6 inches of penetration (Reference 2.5.4-1). However, in the 2023 BWRX-300 SMR investigation, a more objective view was taken as to weathered rock classification from the boring logs, in which a portion of the top of cored rock could be classified in the weathered rock layer thickness, if it was described as highly weathered, exhibited high fracture density and had very poor to poor Rock Quality Designation (RQD).

Subsequent to the 2013 CRN Site investigation, RQD values, ASTM D6032 (Reference 2.5.4-10), shear wave velocity (V_S) values, drill rates and rock core photographs of the 2013 investigation were reviewed to further define the thickness of weathered rock and the corresponding depth to the top of sound rock (hereinafter referred to as rock or bedrock). RQD values equal to or less than 25 percent, representative of very poor quality rock (Reference 2.5.4-10) along with significantly lower-than-average V_S values were also used to define the thickness of weathered rock. Large variations in the thickness of the weathered rock layer at the CRN Site have been observed; in fact, the thickness of the weathered rock from the MP-100 (from the 2013 investigation) set of borings varies from approximately no weathered rock to 19 ft. The maximum thickness of weathered rock at the CRN Site for Unit 1 location is approximately 19.2 ft (MP-106).

Rename and Replace ESPA SSAR Sections 2.5.4.2.1.4 through 2.5.4.2.1.12 with the following:

2.5.4.2.1.4 Witten Formation

The Witten Formation, which was not encountered during the 2013 CRN SMR subsurface investigation drilling program, was encountered in the 2023 investigation, but outside of the power block, along with the Bowen Formation. More details are provided in Reference 2.5.4-66.

2.5.4.2.1.5 Bowen Formation

The Bowen Formation is a maroon calcareous siltstone. Because of its limited thickness and its distinctive color, Hatcher et al. (Reference 2.5.4-6) describe it as a reliable marker for field and subsurface correlations. The 2013 CRN site subsurface investigation generally describes the bedrock as a reddish brown to olive brown, laminated to very thinly bedded calcareous siltstone. A detailed description of the bedrock is contained in Subsection 2.5.1.2.3.

The Bowen Formation was encountered in two borings in the 2013 CRN SMR Site investigation (MP-415 and MP-428) for a total linear footage of 41 ft (Table 2.5.4-1). The top of the formation was encountered in the two borings at elevations of 773 and 765 ft (Table 2.5.1-2R). The thickness of the Bowen Formation is illustrated on the subsurface profile on Figure 2.5.4-2R. The average apparent (vertical) thickness of the formation based on these two borings is estimated at 30 ft (Table 2.5.4-1). The Bowen Formation is outside of the footprint of the power block area (Locations A and B as sited in the CRN ESPA).

Two borings from the 2023 BWRX-300 SMR site investigation encountered the Bowen Formation, with one boring sampling its entire thickness (Reference 2.5.4-67). The true thickness of the Benbolt Formation in U1-B15 is approximately 33 ft (Table 2.5.1-3). Descriptions of the Bowen Formation from the 2023 subsurface investigation are presented in Reference 2.5.4-66.

RQD values for the Bowen Formation range from 14 to 53 percent with average and median values of 26 and 20 percent, respectively, indicative of poor to very poor quality rock.

2.5.4.2.1.6 Benbolt Formation

The Benbolt Formation comprises interbedded fossiliferous nodular limestone, unfossiliferous amorphous micrite within a dark gray siltstone matric, and unfossiliferous calcarenite (Reference 2.5.4-6). The 2013 CRN Site subsurface investigation describes the bedrock as a gray limestone (micrite/wackestone), strong, very thinly to thinly bedded, locally moderately bedded, and nodular limestone interbedded with little to some laminated to thinly bedded calcareous siltstone. A detailed description of the bedrock is contained in Subsection 2.5.1.2.3.

The Benbolt Formation is encountered in the southeastern portion of the power block area (Locations A and B), predominantly in the 100-series borings but also in a few of the 400-series borings. Twenty-five borings penetrated into the Benbolt Formation in the 2013 site investigation for a total linear footage of 3254 ft (Table 2.5.4-1). The top of the formation encountered in the borings ranges in elevation from about 794 to 739 ft (determined from Table 2.5.1-2). The thickness of the Benbolt Formation is illustrated on the subsurface profile on Figure 2.5.4-2R. The average apparent (vertical) thickness of the formation based on the borings is estimated at 330 ft (Table 2.5.4-1).

RQD values for the Benbolt Formation range from 0 to 100 percent with average and median values of 88 and 98 percent, respectively, indicative of good to excellent quality rock. Rock core recovery and RQD values obtained from the borings are summarized in Table 2.5.4-4 and shown on Figure 2.5.4-3.

Descriptions of the Benbolt Formation from the 2023 BWRX-300 SMR subsurface investigation are presented in Reference 2.5.4-66. The Benbolt Formation is the dominant formation in the Unit 1 footprint, having been encountered in 15 of the 16 borings.

2.5.4.2.1.7 Rockdell Formation

The Rockdell Formation is a thick limestone with bedded and nodular chert that transitions with depth to a calcareous siltstone, a fossiliferous nodular limestone and a micritic limestone (Reference 2.5.4-6). The 2013 CRN Site investigation generally describes the bedrock as two units, Unit C and Unit D, based on an 11 to 32 ft thick calcareous siltstone layer that forms the contact between the two units (Reference 2.5.4-1). Units C and D are generally described as gray and brownish-gray, strong, laminated to moderately bedded limestone (micrite/wackestone/grainstone), interbedded with few to little, laminated to very thinly bedded calcareous siltstone. A detailed description of the bedrock is contained in Subsection 2.5.1.2.3. With regard to assigning engineering properties, the Rockdell Formation is considered as a single unit.

The Rockdell Formation is encountered in the central and southeastern portions of the power block area (Locations A and B), predominantly in the 100-series borings but also in some of the 400-series borings. Sixteen borings penetrated into the Rockdell Formation for a total linear footage of 1794 ft (Table 2.5.4-1). The top of the formation encountered in the borings ranges in elevation from about 801 to 577 ft (determined from Table 2.5.1-2). The thickness of the Rockdell Formation is illustrated on the subsurface profile on Figure 2.5.4-2R. The average apparent (vertical) thickness of the formation based on the borings is estimated at 287 ft (Table 2.5.4-1).

RQD values range from 0 to 100 percent with average and median values of 88 and 96 percent, respectively, indicative of good to excellent quality rock. Rock core recovery and RQD values obtained from the borings are summarized in Table 2.5.4-4 and shown on Figure 2.5.4-3.

Descriptions of the Rockdell Formation, (Unit C and D members), which underlines the Benbolt Formation within the Unit 1 footprint, are presented from the 2023 BWRX-300 SMR subsurface investigation in Reference 2.5.4-66.

2.5.4.2.1.8 Fleanor Member (Lincolnshire Formation)

The upper member of the Lincolnshire Formation, the Fleanor Member, comprises maroon, calcareous and shaly siltstone with numerous light gray limestone beds (Reference 2.5.4-6). The 2013 CRN Site investigation generally describes the bedrock as a red, medium strong, laminated to medium bedded, calcareous siltstone with few to little gray micritic limestone layers. A detailed description of the bedrock is contained in Subsection 2.5.1.2.3.

The Fleanor Member is encountered in the central portion of the power block area (Locations A and B), predominantly in the 200-series borings but also in some of the 400-series borings. Twenty-nine borings penetrated into the Fleanor Member for a total linear footage of 2953 ft (Table 2.5.4-1). The top of the Fleanor Member encountered in the borings ranges in elevation from 809 to 381 ft (determined from Table 2.5.1-2). The thickness of the Fleanor Member at the CRN Site is illustrated on the subsurface profile on Figure 2.5.4-2R. The average apparent (vertical) thickness of the member based on the 2013 CRN Site investigation is estimated at 257 ft (Table 2.5.4-1).

RQD values range from 0 to 100 percent with average and median values of 89 and 98 percent, respectively, indicative of good to excellent quality rock. Rock core recovery and RQD values obtained from the borings are summarized in Table 2.5.4-4 and shown on Figure 2.5.4-3.

Descriptions of the Fleanor Member which underlies the Rockdell Formation in the Unit 1 footprint, are presented from the 2023 BWRX-300 SMR subsurface investigation in Reference 2.5.4-66.

2.5.4.2.1.9 Eidson Member (Lincolnshire Formation)

The lower member of the Lincolnshire Formation, the Eidson Member, comprises massive to nodular limestone with bedded and nodular chert (Reference 2.5.4-6). The 2013 CRN Site investigation generally describes the bedrock as a gray, medium strong and strong, laminated to thinly bedded, fresh, argillaceous micritic limestone.

The Eidson Member is encountered in the central and northwestern portions of the power block area (Locations A and B), predominantly in the 200-series borings but also in some of the 400-series borings. Seventeen borings penetrated into the Eidson Member for a total linear footage of 1027 ft (Table 2.5.4-1). The top of the Eidson Member encountered in the borings ranges in elevation from about 809 to 604 ft (determined from Table 2.5.1-2). The thickness of the Eidson Member at the CRN Site is illustrated on the subsurface profile on Figure 2.5.4-2R.

The average apparent (vertical) thickness of the member based on the borings is estimated at 102 ft (Table 2.5.4-1).

RQD values range from 0 to 100 percent with average and median values of 79 and 88 percent, respectively, indicative of good quality rock. Rock core recovery and RQD values obtained from the borings are summarized in Table 2.5.4-4 and shown on Figure 2.5.4-3.

The Eidson Member was not encountered during the 2023 BWRX-300 SMR drilling investigation.

2.5.4.2.1.10 Blackford Formation

The Blackford Formation comprises purplish to dark maroon calcareous siltstone interbedded with light gray calcarenite (Reference 2.5.4-6). The 2013 CRN Site investigation describes the bedrock as two units, the Lower and Upper Blackford. The contact between the Lower Blackford and the underlying Newala Formation is a disconformity. The Lower Blackford is generally described as a gray, locally mottled, strong, laminated to thickly bedded, micritic limestone. The Upper Blackford is generally described as a gray, calcareous siltstone, laminated to moderately bedded, interbedded with little to some limestone with few to little chert beds, lenses and nodules. A detailed description of the bedrock is contained in Subsection 2.5.1.2.3. With regard to assigning engineering properties, the Blackford Formation is considered as a single unit.

The Blackford Formation Member is encountered in the central and northwestern portions of the power block area (Locations A and B), in the 200-series and 400-series borings. Fifteen borings penetrated into the Blackford Formation for a total linear footage of 1554 ft (Table 2.5.4-1). The top of the Blackford Formation encountered in the borings ranges in elevation from 840 to 507 ft (determined from Table 2.5.1-2). The thickness of the formation at the CRN Site is illustrated on the subsurface profile on Figure 2.5.4-2R. The average apparent (vertical) thickness of the formation based on the borings is estimated at 254 ft (Table 2.5.4-1).

RQD values range from 0 to 100 percent with average and median values of 81 and 92 percent, respectively, indicative of good to excellent quality rock. Rock core recovery and RQD values obtained from the borings are summarized in Table 2.5.4-4 and shown on Figure 2.5.4-3.

The Blackford Formation was not encountered during the 2023 BWRX-300 SMR drilling investigation.

2.5.4.2.1.11 Newala Formation

The Newala Formation is the uppermost unit of the Knox Group and comprises predominantly fine to medium grained dolomite with some chert nodules (Reference 2.5.4-6). Hatcher et al. (Reference 2.5.4-6) report that the thickness of the Newala Formation is variable due to the erosional unconformity (disconformity) and indicates the relief on this surface is a minimum of about 230 ft. The 2013 CRN Site investigation generally describes the formation as a fresh, fine to medium grained, gray, locally mottled red, strong to very strong, moderately to thickly bedded crystalline dolomite, with few irregular chert nodules and chert beds. A detailed description of the bedrock is contained in Subsection 2.5.1.2.3.

The Newala Formation is encountered in the northwestern portion of the power block area (Locations A and B), predominantly in the 400-series borings and one 200-series boring (MP-201). Sixteen borings penetrated into the Newala Formation for a total linear footage of 2501 ft (Table 2.5.4-1). The top of the formation encountered in the borings ranges in elevation from approximately 815 to 481 ft (determined from Table 2.5.1-2). Regionally, the thickness of the formation is estimated to range between 900 and 1200 ft (Reference 2.5.4-11). The thickness of the formation at the CRN Site is unknown as none of the borings drilled at the site penetrated the full thickness of the unit (Figure 2.5.4-2R).

RQD values range from 0 to 100 percent with average and median values of 93 and 98 percent, respectively, indicative of excellent quality rock. Rock core recovery and RQD values obtained from the borings are summarized in Table 2.5.4-4 and shown on Figure 2.5.4-3.

The Newala Formation was not encountered during the 2023 BWRX-300 SMR drilling investigation.

2.5.4.2.1.12 Subsurface Profiles

Figure 2.5.4-2R illustrates a typical subsurface profile through the footprint of the proposed Unit 1 at the CRN Site. The profile is constructed perpendicular to the strike of the bedding planes (parallel to the dip direction). The final plant grade elevation of Unit 1 is expected at EL 814.5 ft and the shaft foundation embedment depth is approximately 115 ft below the plant grade elevation, with the planned excavation depth approximately 129.5 ft below grade elevation.

2.5.4.2.3 Laboratory Testing

Replace the first sentence of the first paragraph of ESPA SSAR Section 2.5.4.2.3 with the following:

As with the field exploration, laboratory tests of soil and rock samples were performed previously for the CRBRP and performed as part of the 2013 CRN Site subsurface investigation.

Insert the following after the fourth paragraph of ESPA SSAR Section 2.5.4.2.3:

The 2023 CRN Site investigation was conducted, and geotechnical laboratory testing was performed at various laboratory locations. Laboratory testing was performed in accordance with ASTM standards or other standards, where applicable and as specified by RIZZO. Laboratory testing results are discussed in further detail in Reference 2.5.4-66. Key parameters, including boring logs, lab testing, soil properties, rock properties, downhole geophysical logging, and spectral analysis of surface waves, exhibited consistent results, confirming the reliability and validity of the data set presented in ESPA.

2.5.4.2.4 Engineering Properties

Replace the first paragraph of ESPA SSAR Section 2.5.4.2.4 with the following:

The engineering properties for the existing fill/residual soil, granular backfill, weathered rock and the bedrock within the footprint of the 2013 power block area (Locations A and B in the CRN ESPA) are derived from the 2013 CRN Site subsurface investigation and laboratory testing programs and are provided in Table 2.5.4-21.

2.5.4.2.4.1 Soil Properties

Replace the second sentence of the first paragraph of ESPA SSAR Section 2.5.4.2.4.1 with the following:

The properties are developed based on the results of the laboratory testing program from the 2013 CRN Site investigation program, unless stated otherwise.

2.5.4.2.4.2 Weathered Rock Properties

Replace the first paragraph of ESPA SSAR Section 2.5.4.2.4.2 with the following:

Weathered rock is described in Subsection 2.5.4.2.1.3. The ESPA was prepared assuming the weathered rock would be excavated during construction and selected engineering properties of the weathered rock were developed from in situ testing (2013 CRN Site investigation) and material correlations.

2.5.4.2.4.3 Intact Rock Properties

Replace the last sentence of the first paragraph of ESPA SSAR Section 2.5.4.2.4.3 with the following:

The properties are developed based on the results of the laboratory and field testing programs performed for the CRN Site in 2013.

2.5.4.2.4.4 Rock Mass Properties

Replace the second paragraph of ESPA SSAR Section 2.5.4.2.4.4 with the following:

The properties are developed using the GSI. The application of the GSI classification and Hoek-Brown failure criterion assumes that the rock mass contains several sets of discontinuities that are closely spaced relative to the proposed structure, such that it behaves as a homogeneous and isotropic mass and that a predetermined failure plane does not exist. In other words, while the behavior of the rock mass is controlled by the movement and rotation of the rock blocks separated by intersecting discontinuities, there are no preferred failure directions (Reference 2.5.4-18).

Replace the sixth paragraph of ESPA SSAR Section 2.5.4.2.4.4 with the following:

The rock mass strength and deformation properties are developed using the GSI classifications of the stratigraphic units that are based on a select number of 100-, 200- and 400-series borings drilled at the 2013 CRN Site investigation.

The supplemental site-specific field exploration (2023 CRN Site investigation) and testing have been conducted with considerations on the selected GEH BWRX-300 reactor technology. The data from this additional testing and exploration program allows for the further assessment of the rock mass properties and characterization of the subsurface conditions under the layout of Unit 1 at the CRN Site in more details. Parallel GSI classifications based on the fracture data of the 2023 boreholes show that the GSI results for the Rockdell and Benbolt Formations are consistent with GSI classification performed with the 2013 data for the same two formations. The data from the 2023 CRN Site investigation program, whose results supplement the existing information and datasets, are discussed and compared with the 2013 results in Reference 2.5.4-66.

Renumber the Rock Mass Strength subsection of ESPA SSAR Section 2.5.4.2.4.4 to Section 2.5.4.2.4.5 Rock Mass Strength.

Insert the following after the fifth paragraph of ESPA SSAR Section 2.5.4.2.4.5

Generalized Hoek-Brown failure criterion, rock mass strength calculations were also performed with the 2023 site investigation data. The results of the rock mass strength calculations with the 2023 data are presented in Reference 2.5.4-66. The results indicate that the data are primarily consistent with the 2013 calculation results.

Renumber the Rock Mass Deformation Modulus subsection of ESPA SSAR Section 2.5.4.2.4.4 to Section 2.5.4.2.4.6 Rock Mass Deformation Modulus.

Insert the following after the first paragraph of ESPA SSAR Section 2.5.4.2.4.6:

The summary of strength properties is presented in Table 2.5.4-24.

Insert the following after the third paragraph of ESPA SSAR Section 2.5.4.2.4.6:

The deformation modulus of the rock mass calculations were also performed with the 2023 site investigation data using the same empirical equations as the 2013 data. The results of the deformation modulus calculations with the 2023 data are presented in Reference 2.5.4-66. The results indicate that the data are primarily consistent with the 2013 calculation results, with only minor deviations that can be explained by the depth of the log data and samples used for analysis.

2.5.4.3 Foundation Interfaces

Replace ESPA SSAR Section 2.5.4.3 with the following:

Subsection 2.5.4.3.1 summarizes subsurface investigations performed for the CRBRP, Subsection 2.5.4.3.2 summarizes the 2013 CRN Site subsurface investigation program implemented for the CRN Site, while Subsection 2.5.4.3.3 summarizes the 2023 supplemental subsurface investigation program for the BWRX-300 SMR.

Rename ESPA SSAR Section 2.5.4.3.2.

2.5.4.3.2 2013 CRN Site Subsurface Investigation Program

Replace the first paragraph and the first sentence of the second paragraph of ESPA SSAR Section 2.5.4.3.2 with the following:

The 2013 CRN Site subsurface investigation was performed between June 2013 and March 2014. The investigation was performed over a substantial portion of the CRN Site but predominantly within the footprint of the power block area (Locations A and B in the CRN ESPA). The investigation consisted of a substantial number of exploration points and was originally designed to support the CPA and the locations of the units being sited at that time (Locations A and B). These exploration point locations are identified as the MP-series and are shown on Figure 2.5.4-1R and Figure 2.5.4-2R. The proposed layout for the selected GEH BWRX-300 unit (i.e., Unit 1) has been sited in the vicinity of Location A of power block from the ESPA, allowing to incorporate the existing subsurface investigation data within the footprint of the new site layout.

The scope of the work performed in the 2013 CRN Site investigation program is listed below:

2.5.4.3.2.1 Borings and Soil Samples/Rock Cores

Replace the first and second paragraphs of ESPA SSAR Section 2.5.4.3.2.1 with the following:

The 82 borings drilled at the CRN Site ranged in depth from about 20 to 540 ft. The deep borings, drilled to depths greater than or equal to about 350 ft, are at least 200 ft deeper than the deepest foundation embedment depth targeted in the CRN ESPA, which was not expected to exceed 138 ft (El. 683 ft). These borings sample even a deeper profile under the anticipated elevation of the BWRX-300 RB foundation for the CRN Site, where the deepest foundation embedment depth is not expected to exceed 115 ft (i.e., approximately El. 699 ft) from the finished site grade El 814.5 ft. Borings include the MP-series borings (100-, 200-, and 400-series) and the CC-B series borings. With the exception of six of the borings (MP-111 PS; MP-111 UD; MP-122 PS-A; MP-122 PS-B; MP-122 UD-A, and MP-122 UD-B) that were drilled in soil only, all of the borings were drilled in soil and extended into the bedrock.

The 100- and 200-series borings drilled at the site are located within the footprint of the CRN Site power block area in Locations A and B, respectively. It is noted that Locations A and B in the ESPA were sited as a general placement without consideration for a specific reactor technology. A number of the 400-series borings are also within the footprint of the 2013 power block area (Locations A and B), while the majority is in the surrounding areas. Seven of the borings (MP-112, -113, -212, -213, -424, -425, and -425) were drilled at inclinations of between 25 and 29 degrees from the vertical. (Figure 2.5.4-1R).

2.5.4.3.2.2 Observation Wells/Well Tests

Replace the first sentence of the first paragraph of ESPA SSAR Section 2.5.4.3.2.2 with the following:

Forty-four groundwater wells were installed at the CRN Site in the 2013 investigation.

2.5.4.3.2.6 Direct Shear Tests

Insert the following after the last sentence of ESPA SSAR Section 2.5.4.3.2.6:

Table 2.5.4-7 shows the number of samples and rock formations selected for direct shear tests.

Add new Section 2.5.4.3.3:

2.5.4.3.3 2023 Supplemental Field Investigation Program

The 2023 supplementary investigation program was performed during the period of June 2023 to September 2023 to acquire additional technology specific geotechnical information for a General Electric - Hitachi Nuclear Energy (GEH) small modular reactor (SMR) at the Clinch River Nuclear (CRN) site. The 2023 CRN Site investigation was developed to supplement the existing geotechnical database for the CRN Site from the two prior site investigations (References 2.5.4-1, 2.5.4-2 and 2.5.4-3) and to gain technology specific geotechnical information at specific locations where it was not already available. The borings are identified as the U1-B series and are shown on Figure 2.5.4-1R and Figure 2.5.4-2R.

The principal components and sequence of work related to the completion of the supplemental field investigation activities at the CRN Site were as follows:

- Continuous rock and sediment sampling in 16 geotechnical boreholes
- Undisturbed soil sampling in 11 boreholes
- Borehole geophysical surveys in 8 boreholes
- Borehole closure
- Surface geophysical surveys (Spectral Analysis of Surface Waves)
- Site Survey (initial and as-built)
- Laboratory testing of testing of boring soil and rock core samples.

The results of 2023 CRN Site investigation were used to develop engineering properties for subsurface layers based on field observations and laboratory testing results. Analysis of the results of the 2023 site investigation are presented in Reference 2.5.4-66.

2.5.4.4 Geophysical Surveys

Replace ESPA SSAR Section 2.5.4.4 with the following:

Subsection 2.5.4.4.2 summarizes geophysical investigations performed for the CRBRP, Subsection 2.5.4.4.3 summarizes the 2013 CRN Site geophysical program implemented at the CRN Site, while Subsection 2.5.4.4.3 summarizes the 2023 BWRX-300 SMR geophysical program implemented at the CRN Site.

Rename and Replace ESPA SSAR Section 2.5.4.4.2 with the following:

2.5.4.4.2 Geophysical Surveys for the 2013 CRN Site Investigation

Subsection 2.5.4.4.3.1 summarizes the methods used and results of surface geophysical testing that were performed in the 2013 CRN Site investigation program. Subsection 2.5.4.4.3.2 summarizes the methods used and results of the downhole geophysical testing that were performed at the CRN Site in 2013.

Add new Section 2.5.4.4.3:

2.5.4.4.3 Geophysical Surveys for the 2023 Supplemental Site Investigation

Subsection 2.5.4.4.3.1 summarizes the methods used and results of surface geophysical testing that were performed in the 2023 Supplemental CRN Site investigation program. Subsection 2.5.4.4.3.2 summarizes the methods of the downhole geophysical testing that were performed at the CRN Site in 2023.

2.5.4.4.3.1 Surface Geophysical Testing

The 2023 surface geophysical program consisted of active-source spectral analysis of surface waves (SASW) testing performed at three (3) array locations on the site. The active and passive measurements were combined to develop shear wave velocity profiles. The surface geophysical program test results are provided in Reference 2.5.4-67. Further discussion and analysis of these tests are discussed in Reference 2.5.4-66.

2.5.4.4.3.2 Downhole Geophysical Testing

Downhole geophysical testing was performed during the 2023 Supplemental Site Investigation in 8 geotechnical boreholes involving the following testing:

- V_P and V_S (Suspension P-S velocity logging)
- Downhole Seismic Velocity Testing

- Acoustic televiewer (ATV) and deviation data
- Conductivity and natural-gamma data
- Caliper and natural-gamma data
- Fluid temperature, fluid conductivity and natural-gamma data

Descriptions of the testing methods and subcontractor reports are provided in Reference 2.5.4-67. Further discussion and analysis of these tests are discussed in Reference 2.5.4-66.

2.5.4.5 Excavation and Backfill

Replace the fourth bullet in ESPA SSAR Section 2.5.4.5 with the following:

- Quality Control

2.5.4.5.1 Extent of Excavations, Fill and Slopes

Replace ESPA SSAR Section 2.5.4.5.1 with the following:

Existing elevations within the investigated 2013 CRN SMR power block areas shown in Figure 2.5.4-1R, range from 855 (MP-406) to 780 ft (MP-207, MP-211). These relatively large variations in the existing surface elevations occur over a vast area at the CRN Site. Topography generally slopes gently downward from northwest to southeast as shown on Figure 2.5.4-1R. The approximate ground surface and site stratigraphy are shown on Figure 2.5.4-2R, a cross-section through the power block area orientated approximately perpendicular to strike. The proposed Unit 1 at the CRN Site is located in close proximity of Location A (as cited in the CRN ESPA); therefore, the data from the MP-100 group of borings provide a more representative value for range of existing surface elevations at the proposed Unit 1 location. Based on data listed in Table 2.5.4-3, the existing surface elevation measured at the MP-100 boring series varies between approximately 797 to 802 ft, with an average of around 800 ft (computed average elevation of 799.2 ft). Finished plant grade elevation is expected at elevation 814.5 ft. The bottom of the basemat of the deeply embedded seismic category I structure, i.e., RB, is expected not to exceed a depth of 115 ft below finished grade, i.e., elevation 699.5 ft.

Existing fill/residual soil and weathered rock vary in thickness within the power block area and are generally thickest in the central and southern portions of the site as shown on Figure 2.5.4-2R. Bedrock is shallowest at the northern portion of the Unit 1 area. Table 2.5.4-26R highlights the variability in the subsurface stratigraphy by summarizing the strata thickness and variability at Locations A and B. It is noted that the proposed location for Unit 1 of the selected technology has been sited in the vicinity of Location A. The construction of the vertical shaft for the RB requires a deep excavation in both soil and rock; however, the horizontal (lateral) extent of this excavation is limited as imposed by the diameter of the vertical shaft and in part to the method of construction (i.e., providing adequate space for the construction). Excavation sidewalls are expected to be vertical or near-vertical due in part to the depth of excavation,

requiring the use of surface mounted cranes. The floor of the excavation at the RB location is expected to be irregular since hard unweathered rock will be encountered, requiring the use of dental concrete to establish a level grade.

The final plant grade elevation for the proposed Unit 1 is expected to be at elevation 814.5 ft, which is approximately 14.5 ft higher than the average existing site grade in the vicinity of Unit 1 location at CRN Site. Engineered fill will be used to raise the existing grade to the final plant grade elevation. Additionally, the lateral extent of the backfill will extend to accommodate the construction of the multiple surface (near-surface) built structures around the RB shaft, including the Radwaste, Control, Service, and Turbine Buildings.

The construction of the RB requires preparing a vertical deep shaft by excavating predominantly in an unweathered rock formation (i.e., Benbolt). However, in order to reach the unweathered rock, shallow soil and weathered rock layers must be excavated. As the excavation for the RB proceeds, in order to provide a stable excavation condition in the existing fill and residual soil, as well as retain the engineered fill in the vicinity of the RB shaft, an excavation and construction support system is required. At this preliminary stage, compression rings are considered in a conceptual layout as soil retaining systems. Concrete backfill may be used for dental concrete as well as backfilling around the RB structure.

Excavation of soil and rock at the CRN Site is discussed in the following paragraphs. Design of the excavation and backfill, and subsequently the appropriate construction method, is done during the detailed design stage of the project.

2.5.4.5.2.1 Excavation in Soil

Replace ESPA SSAR Section 2.5.4.5.2.1 with the following:

Excavation in existing fill/residual soil can be made with conventional earthmoving equipment. Excavation must adhere to regulations from Occupational Safety and Health Administration (OSHA), 29 CFR 1926, Safety and Health Regulations for Construction. The excavations in soil for the deep vertical shaft of the RB may require sloped layback approach or vertical cuts supported with temporary systems (such as soldier piles with lagging) and subsequently retained with permanent solutions (such as compression rings). The final selection and design of the appropriate support system is done at the detailed design stage of the project. The side slopes of the ramp for construction access made in soil are checked against slope stability and recommended to be excavated at slope angles of 3 (horizontal) to 1 (vertical).

2.5.4.5.2.2 Excavation in Weathered Rock

Replace ESPA SSAR Section 2.5.4.5.2.2 with the following:

Excavation in the weathered rock can be achieved using conventional excavating equipment. Excavation support methods similar to those used for soil can be used for weathered rock. As described in Subsection 2.4.12, groundwater is generally encountered above the top of bedrock,

within the weathered rock. Groundwater control as described in Subsection 2.5.4.6.2 is required during excavation and for excavation support.

2.5.4.5.2.3 Excavation in Rock

Replace ESPA SSAR Section 2.5.4.5.2.3 with the following:

Excavation in rock is likely to be made by using controlled blasting techniques. As noted by Reference 2.5.4-8 the majority of rock excavation (1.1 million cubic yards of primarily laminated siltstone and limestone) for the CRBRP was made by blasting. To minimize rock excavation and provide crane access to the bottom of the excavation, 75-ft high near-vertical rock slopes in the north, south and east portions of the excavation were required. Methods included production and perimeter blasting. Production blasting, to remove the bulk of the excavation, was conducted in 13-ft lifts with burden distances of 5 to 7 ft and spacing between holes of 6 to 8 ft. Perimeter blasting was conducted to form the finished excavation face and foundation grade. Perimeter blast holes were spaced at 2-ft intervals.

The near-vertical rock slope was stabilized with rock bolts. Reference 2.5.4-8 reports that the original rock bolt design for the foundation and excavation support system was based on subsurface data. As the excavation proceeded, geologic mapping of exposed rock surfaces enabled a redesign of the rock bolting program.

Slope movement and foundation performance was monitored with an extensive instrumentation program during and after the excavation. Instrumentation included 20 inclinometers to monitor slope movement around the perimeter of the excavation, 34 horizontal extensometers to monitor deep seated wedge movement of the rock slopes, two vertical extensometers to measure heave and settlement, and 25 piezometers to measure hydrostatic levels behind the excavation slopes and at foundation grade (Reference 2.5.4-8).

The foundation of the RB for the proposed Unit 1 is expected to be resting on rock in Benbolt formation. The construction of the vertical RB shaft will require deep excavations into this rock formation. Therefore, a blasting program specific to this rock type and its rock mass characteristics will be designed to facilitate the excavation similar to CRBRP. As the excavation in rock continues, the exposed faces will be mapped to determine the potential need for additional support and stabilization systems in rock.

The excavation in rock is considered as disturbed zone in the analysis. It is anticipated that the mat foundation overlays a zone of disturbed material with D=0.7, to account for disturbed rock mass from blasting and stress relief. D value mentioned above is a factor which depends on severity of disturbance caused by blasting and stress relaxation during excavation. The value ranges between 0 and 1, where 0 is used for undisturbed in situ rock masses and 1 is used for very disturbed rock masses. The extent of the disturbed zone is unknown and dependent upon the blasting technique used. However, it is unlikely to extend to depths beyond 10 to 15 ft below the foundation level. Conservatively, this zone was assumed to be 25 ft thick below the foundation, and the D value used in the analysis is conservatively chosen to be 0.7.

It is noted that the supplemental site-specific field exploration (2023 CRN Site investigation) and testing was planned and performed with considerations on the selected reactor technology. The objective of the additional data was to supplement the existing information and datasets in characterizing the subsurface conditions. Data from the recent site investigation program are presented in Reference 2.5.4-66. Design of the excavation sequences and methods, excavation support (such as rock bolting, if necessary), and instrumentation and monitoring system will be developed during the detailed design stage. This design accounts for the specific rock units encountered in the excavation, including the dip angle of these units.

2.5.4.5.3 Backfill Sources

Replace ESPA SSAR Section 2.5.4.5.3 with the following:

Granular backfill consists of a processed graded aggregate meeting the gradation requirements of Type A aggregate of the Tennessee Department of Transportation (TDOT) Standard Specifications for Road and Bridge Construction (Reference 2.5.4-37) Section 303 and Section 903. Given the large amount of rock that needs to be excavated across the site, it may be advantageous to set up a crushing and blending plant onsite to produce the crushed aggregate to the required gradation specification. Otherwise, the graded aggregate is imported from nearby quarries.

A detailed field and laboratory test program shall be conducted during the design stage to evaluate backfill sources and their engineering properties. This program will evaluate the use of onsite excavated rock as well as imported backfill. In fact, soundness and abrasion tests along with laboratory tests on characterization of some of the chemical properties of samples from the Benbolt formation have been performed as part of the recent supplemental site investigation program. These data, presented in Reference 2.5.4-67, will assist in deciding on the suitability of the excavated rock as a source for backfill. The backfill evaluation program will consider gradation (grain size distribution), density, soundness, durability, strength, and the dynamic properties of the backfill. A test pad will be constructed to establish placement and compaction methods. It is expected that the granular backfill is compacted to at least 95 percent of the maximum dry density as determined by the modified Proctor test (ASTM D1557, Reference 2.5.4-15) and that the moisture content of the compacted fill is within 3 percent of its optimum moisture content.

Rename and Replace ESPA SSAR Section 2.5.4.5.4 with the following:

2.5.4.5.4 Quality Control

Details, including identification of quality requirements and industry standards, regarding SC1 backfill material and placement specifications will be developed during the detailed design stage. Quality control measures related to backfill will also be developed during the detailed design stage. General requirements for backfill and subgrade quality control are provided in the following paragraphs.

2.5.4.6 Groundwater Conditions

2.5.4.6.1 Groundwater Measurements and Elevations

Replace the first sentence of the second paragraph of ESPA SSAR Section 2.5.4.6.1 with the following:

Groundwater observation wells were installed at the CRN Site as part of the 2013 CRN Site subsurface investigation program.

2.5.4.7 Response of Soil and Rock to Dynamic Loading

2.5.4.7.2 Velocity Profiles

Replace ESPA SSAR Section 2.5.4.7.2 with the following:

Various geophysical surveys were conducted in 2013 at the CRN Site to characterize in situ dynamic properties of the soil and rock, including seismic refraction and reflection, and P-S Suspension logging as described in Subsection 2.5.4.4.3. The P-S Suspension logging method was used to collect V_S and V_P measurements in the soil and rock. Figures 2.5.4-5 and 2.5.4-6 present V_S and V_P profiles for each stratigraphic unit. These V_S and V_P profiles in unweathered rock have been developed and subsequently used to form the velocity profiles at Locations A and B of the 2013 layout, as sited in the CRN Site ESPA. The new proposed layout of Unit 1 with the selected technology at the CRN Site is located in the vicinity of Location A. In fact, the proposed location of the RB vertical shaft is surrounded by borings MP-110, MP-112, and MP-113 which lie within the extent of Location A. The velocity profiles for Location B are also presented as they provide insight into the subsurface conditions.

Supplemental site-specific field exploration (2023 CRN Site investigation) and testing have been conducted to supplement the existing data set. This investigation has been designed and implemented based on the proposed Unit 1 layout with the GEH BWRX-300 reactor technology. The additional testing and exploration program included additional downhole suspension P-S velocity logging and conventional downhole surveys performed in eight borings. This supplemental geophysical investigation provided additional data that confirms the previously acquired information and serves to verify the wave velocity profiles and other dynamic properties of the Benbolt and Rockdell formations, at the CRN Site.

Downhole seismic testing was performed in six borings during the 2023 BWRX-300 SMR site investigation to determine P-wave and S-wave velocity profiles. Seismic waves generated on the surface were monitored during downhole testing at depth intervals of 10 ft using a single borehole geophone lowered and raised in the borehole.

Discussion of these geophysical investigations and the associated velocity profiles can be found in Reference 2.5.4-66 and Reference 2.5.4-67.

2.5.4.7.2.1 Shear Wave Velocity Profiles

Replace ESPA SSAR Section 2.5.4.7.2.1 with the following:

The V_S profiles used to develop the performance-based ground motions for the BWRX-300 SMR site are described in Subsection 2.5.2.5.1. Note they differ in the shallow section from the V_S profile developed for Location A.

Details on developing the stratigraphy and V_S profiles for Locations A and B of the 2013 CRN SMR layout within the rock units are provided in this section for context and because the deeper portion of the V_S profile of Location A was adopted for the base-case V_S profile for the BWRX-300 site (Subsection 2.5.2.5.1). These profiles were developed by considering the top of the profile (depth = 0) at the top of unweathered rock at each location and using site-measured V_S data, V_S data measured in similar nearby geologic units, and estimated V_S values from literature from the top of unweathered rock to Precambrian basement rock.

The geologic cross-section illustrating the shallow portion of these profiles is shown on Figure 2.5.4-12 with the full depth shown on Figure 2.5.4-13. The best estimate (mean) base-case V_S profile for the shallow geologic units (rock) was developed for each area by computing the lognormal mean profile for the measured V_S data from the boreholes taken in the area, or just outside the area (within 100 ft), as shown in Figure 2.5.4-11 where the V_S data for each borehole was normalized to the top of unweathered rock, zero depth. The associated borehole data and lognormal average V_S profile for Locations A and B (of the 2013 CRN SMR layout) are shown on Figures 2.5.4-14 and 2.5.4-15, respectively with the top of the profile (depth = 0) at the top of unweathered rock.

Boreholes whose data were used in developing the V_S profile in Figure 2.5.4-14 (Location A) fall within the footprint of the layout of Unit 1 or in its very close proximity and approximately envelop the RB. In fact, boring MP-101 borders the Control buildings, MP-102 is to the west of the RB and Turbine building, MP-111 is located immediately to the North of the Control building. Borehole MP-120 is slightly to the East (considering the plant North) of the Radwaste building. Below the measured data and extending into the Newala, average V_S values provided in Table 2.5.4-21 were assigned to the underlying geologic units. Unless supported by measured data, the Newala Formation and the remainder of the Knox Group were assigned a V_S of 11,000 fps. These profiles are shown on Figures 2.5.4-16 and 2.5.4-17 for Locations A and B, respectively.

Interpretation of the 2023 downhole velocity data reveals that in general, the V_S values range from 1,125 to 9,800 ft/sec, with an average velocity of 5578 ft/sec. No significant velocity reversals with depth were observed. A table of the identified depth intervals (layers), the subsequent seismic velocities over the defined layers, the calculated Poisson’s ratio as well as a plot of the V_S profiles at all seven boreholes is presented in Reference 2.5.4-66. The raw data is presented in Reference 2.5.4-67.

Prior to the 2023 BWRX-300 SMR site investigation, limited V_S data was available for the deep geologic units as site specific SASW surveys were not completed during the 2013 Site investigation. Consequently, measured data from spectral analysis of surface waves (SASW) surveys in the Conasauga shale, Pumpkin Valley shale, and Rome Formation at the nearby Watts Bar facility were used. These data were taken from depths of 500 and 1500 ft and adjusted to the CRN Site using generic V_S profiles for central and eastern U.S. hard rock (Reference 2.5.4-58) and applied to the deeper geologic units of the profiles. These profiles are shown on Figures 2.5.4-18 and 2.5.4-19 for Locations A and B, as sited the ESPA, respectively.

Epistemic uncertainty in the mean base-case (best estimate) profiles is accounted for with upper-and lower-range base-case profiles as described in Subsection 2.5.2.5.1.1.

SASW testing was performed along three (3) array locations on the site during the 2023 Site investigation using a Common-Middle-Receiver Geometry where the second receiver in the array is fixed while the location of the other receivers and source are varied to yield different spacing configurations. Forward and reverse source shots were used for several of the spacing configurations to minimize internal phase shifts between receivers. A detailed description of the surveys is presented in Reference 2.5.4-67.

Interpretation of the SASW velocity data reveal that the three locations can generally be described as a three-layer system with a 25-39 ft thick low velocity layer where V_S is less than 1300 ft/sec, overlying a 67-99 ft thick layer with V_S ranging from 2,230 to 2,840 ft/sec, then V_S increases to between 7,675-8,060 ft/sec down to a modeled depth of 960 ft. The V_S data and related profiles from the SASW survey, along with greater discussion is presented in Reference 2.5.4-66.

Engineered fill will be used to raise the current site grade elevation to the final site grade. The mechanical properties of the backfill will be determined at the detailed stage of the design. As described in Subsection 2.5.2.5.1, at this stage the V_S model for the backfill has been estimated empirically from literature or other site response analysis studies.

2.5.4.7.2.2 Compression Wave Velocity Profiles

Replace ESPA SSAR Section 2.5.4.7.2.2 with the following:

The V_P profiles in rock at the CRN Site are developed in a similar manner to the V_S profiles. The unit V_P profiles as presented on Figure 2.5.4-6 are developed based on the site stratigraphy for the corresponding stratigraphic units as characterized in the 2013 CRN Site investigation program. Table 2.5.4-11 also presents the P-wave velocity of the weathered rock and existing fill/residual soil at the CRN Site.

Interpretation of the downhole velocity data reveal that in general, the V_P values from 2,040 to 21,270 ft/sec with an average of 11,597 ft/sec. No significant velocity reversals with depth were observed. Discussion of the V_P results as well as a plot of the V_S profiles at all seven boreholes is presented in Reference 2.5.4-66 while the raw data is presented in Reference 2.5.4-67.

V_P results were not directly measured with the SASW method, so the V_P values in the table were computed using an assumed Poisson's ratio for each layer. The V_P data from the SASW survey, along with greater discussion is presented in Reference 2.5.4-66.

2.5.4.7.3 Dynamic Laboratory Tests

Insert the following after the first paragraph of ESPA SSAR Section 2.5.4.7.3:

Resonant column torsional shear (RCTS) tests conducted as part of the 2023 BWRX-300 site investigation have been completed by the University of Texas at Austin (Reference 2.5.2-254 and Reference 2.5.2-255). Ten rock samples collected by S+ME were tested. The samples were dynamically tested to evaluate the linear and nonlinear dynamic properties in shear. The effects of 1) isotropic confining pressure, 2) time of confinement, and 3) shearing strain amplitude on the shear modulus (G) and material damping ratio (D) were evaluated. The variations of shear-wave velocity, shear modulus (Gmax) and material damping ratio at small strains were analyzed for all ten samples. MRD curves were estimated based on the RCTS results.

2.5.4.7.4.1 Material Damping and Shear Modulus

Replace ESPA SSAR Section 2.5.4.7.4.1 with the following:

A detailed description of the shear modulus reduction and damping (MRD) curves at the CRN Site for the engineered fill, existing fill and residual soil, weathered and unweathered rock is provided in Subsection 2.5.2.5.3.

2.5.4.7.4.2 Kappa

Replace the second through fifth paragraphs of ESPA SSAR Section 2.5.4.7.4.2 with the following:

Subsection 2.5.2.5.2 describes the estimation of kappa.

Subsection 2.5.2.5.3.1 provides a discussion of how kappa is assigned to each shear wave velocity profile.

2.5.4.7.5 Rock Column Amplification/Attenuation Analysis

Replace ESPA SSAR Section 2.5.4.7.5 with the following:

The soil/rock column amplification/attenuation analysis is described in Subsection 2.5.2.5. The generalized soil/rock column for the site response analysis at the CRN Site consists of engineered fill, existing fill/residual soil, in-situ weathered rock, and in-situ unweather rock. This analysis considers a deep rock profile, from the top of unweathered rock to the Precambrian basement rock, with the stratigraphy shown on Figures 2.5.4-12 and 2.5.4-13. Moreover, the amplification factors at the RB foundation level, top of the unweathered rock level, and the final

plant grade level (Elevation 814.5 ft) are computed. The V_S profiles, material damping, shear modulus, and kappa values used in this analysis are described in Subsections 2.5.4.7.4 or 2.5.2.5.1.

Unit weights are described in Subsection 2.5.2.5.1.2.

2.5.4.8 Liquefaction Potential

Replace the fourth paragraph of ESPA SSAR Section 2.5.4.8 with the following:

The SC1 structures (RB) at the CRN Site are embedded at a depth expected not to exceed 115 ft below final grade (El. 699.5 ft). Sound rock (bedrock/rock below the weathered rock) is located at an average elevation of 20 to 30 ft below the existing ground surface around the RB location, more than 70 ft above the foundation level. Furthermore, if any dental work is required to prepare the foundation surface, dental concrete is used. Liquefaction cannot occur in sound rock or concrete; therefore, there is no potential for liquefaction in the foundation materials in unweathered rock.

Replace the fifth paragraph of ESPA SSAR Section 2.5.4.8 with the following:

Subsection 2.5.4.5 describes the plan for backfilling at the CRN Site. Concrete, if used for backfilling, does not pose a potential liquefaction issue. Granular backfill is expected to be used to raise the existing ground surface to the final plant grade elevation. The granular backfill shall be compacted to at least 95 percent of the modified Proctor value. Based on the gradation and degree of compaction, this backfill is not considered to be susceptible to liquefaction.

Replace the seventh paragraph of ESPA SSAR Section 2.5.4.8 with the following:

Test results from Atterberg limits conducted on representative soils from the 2013 CRN SMR Site investigation are plotted on Figure 2.5.4-10 along with the Polito criteria for liquefiable soils (Reference 2.5.4-41), whereby plasticity is the key factor. If this requirement, whether measured in terms of liquid limit (LL) or plastic limit (PL), is met, the soil does not appear to be susceptible to flow liquefaction. A PL of 10 and a LL of 30 are used as threshold values. All of the CRN Site soils from the 2013 subsurface investigation plotted on Figure 2.5.4-10 fall outside the proposed zone of liquefiable soils and therefore are not susceptible to liquefaction by the Polito criteria.

Replace the eighth paragraph of ESPA SSAR Section 2.5.4.8 with the following:

In summary, rock, backfilled with concrete and compacted (engineering) granular backfill are not susceptible to liquefaction. The CRN Site soils, which include the existing fill and residual soil that consist predominately of cohesive, fine-grained material, are not considered susceptible to liquefaction.

2.5.4.9 Earthquake Design Basis

Replace ESPA SSAR Section 2.5.4.9 with the following:

The development of the site-specific response spectra for Unit 1 at the CRN Site is described in Subsection 2.5.2.5.8. The associated vertical spectra are computed with the V/H ratios as described in Subsection 2.5.2.5.6.

2.5.4.10 Static and Dynamic Stability

Replace the second paragraph of ESPA SSAR Section 2.5.4.10 with the following:

Subsection 2.5.4.1.1 describes the stratigraphy at the site. The site is underlain with a succession of stratigraphic units that generally strike N63°E with a dip angle of 33 degrees. Rocks belonging to the Knox Group outcrop to the northwest and progressively younger rocks belonging to the Chickamauga Group outcrop to the southeast. The stratigraphic units at the CRN Site, from northwest to southeast, include the Newala Formation, Blackford Formation, Eidson and Fleanor Members, Rockdell Formation, Benbolt Formation, Bowen Formation and Witten Formation. Benbolt and Rockdell formations are shallowest rock layers under the footprint of the proposed Unit 1 layout. The average thickness of these units, based on the 2013 CRN investigation data, is presented in Table 2.5.4-1.

Replace the fourth and fifth paragraphs of ESPA SSAR Section 2.5.4.10 with the following:

Overlying the dipping bedrock units, a layer of weathered rock and existing fill/residual soil is encountered at the CRN Site. These materials are described in Subsection 2.5.4.2.4. Existing site grades vary within and around the footprint area of Unit 1 with an average elevation of approximately 800 ft. Compacted granular fill is used to establish the expected finished grade and raise the existing surface elevation to the target elevation of 814.5 ft.

Due to the dipping strata at the CRN Site, the stratigraphic units underlying the Unit 1 footprint vary depending on location. For this reason, the location of Unit 1 in the power block area, in the vicinity of Location A of ESPA, is evaluated for static and dynamic stability of SC1 structure with a foundation embedment of 115 ft below finished grade (El. 699.5 ft) and excavation depth is estimated to be at El. 685 ft.

Replace the seventh paragraph of ESPA SSAR Section 2.5.4.10 with the following:

A Three-dimensional (3D) Finite Element (FE) Foundation Interface Analysis (FIA) was developed to simulate the actual subsurface conditions and construction sequences to provide insights into different aspects including the settlement and heave, bearing capacity, lateral earth pressure, and hydro-static pressure under the footprint of Unit 1 at the CRN Site in Subsection 2.5.4.12. The FIA is used for the evaluation of settlement and heave in Subsection 2.5.4.10.2 and to check the response to amplified service loads in Subsection 2.5.4.10.1.1 and Subsection 2.5.4.10.1.2. The foundation response to the incremental loads provides valuable insights into the high capability of rock in resisting loads. The

layout of the selected technology for Unit 1 at the CRN Site (i.e., vertical deep shaft surrounded by surface-founded structures), and site stratigraphy (combination of inclined layering of rock with surficial soil) might render some of the conventional methods for estimating bearing capacity and settlement inapplicable. The FE model attempts to simulate the actual CRN Site subsurface geologic conditions with inclined rock units beneath foundations, impact of excavation on rock disturbance, including a weakened interface between rock units. Rock mass properties based on GSI are considered in evaluating bearing capacity and settlement and heave.

2.5.4.10.1 Bearing Capacity

Replace ESPA SSAR Section 2.5.4.10.1 with the following:

The evaluation of the bearing capacity at the CRN Site was presented in Subsection 2.5.4.10.1 of the CRN Site ESPA. In fact, bearing capacity at Locations A and B were computed by considering a plant parameter envelope (PPE). With the selected GE Hitachi design of BWRX-300 reactor technology, the proposed layout of Unit 1 at the CRN Site consists of a deeply embedded RB vertical shaft with a foundation constructed in the Benbolt formation and several surface-founded structures surrounding the shaft.

The evaluation of bearing capacity of rock is well documented in the literature (References 2.5.4-43, 2.5.4-44, 2.5.4-45, 2.5.4-47, 2.5.4-48, and 2.5.4-49). While authors present different methods, each method generally considers intact rock properties and rock mass properties. As mentioned in the previous section, the proposed layout for Unit 1 at the CRN Site (i.e., vertical deep shaft surrounded by surface-founded structures) as well as the site stratigraphy (combination of inclined layering of rock with surficial backfill), create a condition that deviates from the assumptions in developing the empirical methods for estimating bearing capacity. Therefore, three-dimensional finite element (FE) modeling is used to complement results from traditional approaches in an attempt to capture conditions such as inclined rock units beneath foundations, impact of excavation on rock disturbance, and effects of interfaces at the CRN Site.

The intact rock properties, obtained from laboratory testing, are described in Subsection 2.5.4.2.4.3 and include unit weight, specific gravity, Poisson's ratio, unconfined compressive strength, elastic modulus, and shear modulus. The rock mass properties which account for the in-situ condition of the rock mass are described in Subsection 2.5.4.2.4.4. These properties include rock mass strength and rock mass deformation modulus. The rock mass strength is developed using the Hoek-Brown failure criteria (Reference 2.5.4-19) and the GSI classification system. The rock mass deformation modulus is developed using empirical equations and a combination of the intact elastic modulus, GSI and a disturbance factor (D). Both of these approaches are described in detail in Subsection 2.5.1.2.6.2.

2.5.4.10.1.1 Ultimate Bearing Capacity

Replace ESPA SSAR Section 2.5.4.10.1.1 with the following:

Ultimate bearing capacity (qu) of the RB foundation is estimated using the bearing capacity equations presented by the U.S. Army Corps of Engineers (USACE), Reference 2.5.4-43. Equation 2.5.4-6 is applicable to a foundation bearing on a moderately dipping (20 to 70 degrees from foundation plane) jointed rock mass with general shear failure along joints or a highly jointed rock mass with general shear failure on irregular failure surface through the rock mass.

$$q_u = 0.5\,\gamma\,\beta\,N_\gamma F_{\gamma d} + \gamma\,D\,N_q F_{qd} \qquad \text{Equation 2.5.4-6}$$

where:

N_γ and N_q are rock capacity factors as function of the friction angle ϕ,

$F_{\gamma d}$ and F_{qd} are the embedment factors,

B and *D* denote the depth of foundation below ground level and foundation width, and

γ represents the total unit weight.

With the dipping bedrock and identifiable joint sets, Equation 2.5.4-6 is adequately suited to calculate bearing capacity. It is noted that considering the depth of two times the width of the RB foundation (2B) as the estimate of the influence depth, the influence depth will be sampling both Benbolt and Rockdell rock formations below the RB foundation. The general non-uniformity of the rock formations (with the presence of the bedding plane) below the foundation level is recognized as a limitation of this approach.

To mitigate the limitations of the conventional methods, a three-dimensional finite element model was generated to investigate the bearing capacity of the RB foundation. The finite element model developed for Unit 1 incorporates all the surface-founded structures, the RB, and the geometry of the most significant geological and geotechnical units anticipated within the Site. Figure 2.5.4-29R presents the Finite Element 3D model mesh for Unit 1. The model comprises several construction stages that together track the changes in the effective stress, total strain, and displacement fields generated by the excavation of the vertical RB shaft, lowering the groundwater level, material disturbances in the vicinity of the RB's shaft due to blasting, construction of the RB walls and backfilling, restoring of the groundwater table, and anticipated building loads.

The highly sophisticated three-dimensional model demands significant computational resources and substantial computational times. As a result, its usage is mainly reserved to examine the response of the RB and the bearing capacity modeling of the surface founded structures were performed using separate 2D simulations.

When evaluating the bearing capacity of the RB foundation in the 3D FE model, incremental loads up to 11 times the expected service load were applied to the foundation (the service load is estimated at 8.4 ksf). Figure 2.5.4-41 and Figure 2.5.4-42 illustrate the FE mesh and load conditions of the RB mat at the last stage of the simulation. The results were further examined to evaluate the development of plastic zones below the RB's foundation. It was observed that the distribution of the plastic points and the effective plastic strain field within the rock units did not indicate a failure status; therefore, the augmented load is still below the limit capacity.

Two-dimensional (2D) numerical models were developed to evaluate the bearing capacity of surface-founded structures surrounding the RB. These 2D models adequately capture the evolution of the failure surfaces within the uppermost shallow geotechnical layer and the kinematic constraint imposed by the rigid base, which would be otherwise inaccurate using traditional bearing capacity equations. For these structures, the bearing capacity calculation from 2D models follows a load control approach similar to the one presented for the RB. However, since these models are inherently less computationally demanding, pushing the foundations to reach or to get close to the limit state is possible (i.e., numerical instability matches material collapse). A second alternative incorporates the Strength Reduction Method (SRM) and the Stress Analysis Method (SAM) techniques at each load increment. The 2D and 3D numerical analyses were conducted using Midas GTS-NX. Additionally, in some cases for the evaluation of the static bearing capacity of the surface founded structures, PLAXIS 2D was also used.

2.5.4.10.1.2 Allowable Bearing Capacity

Replace ESPA SSAR Section 2.5.4.10.1.2 with the following:

Allowable bearing capacity (q_a) is defined as the ultimate bearing capacity divided by a factor of safety (FS). A FS of 3 is applied to each of the methods described above.

A general bearing failure of the RB foundation is ruled-out due to a net decrease in the bearing pressure at the foundation level. The amount of unloading by removing rock and soil to construct the RB foundation (foundation approximately 115 ft below final plant grade) is comparable to the pressure from the RB structure (a value of 8.4 ksf is anticipated as the load from the structure). Thus, the net change in pressure at the foundation level is expected to be smaller than the anticipated applied pressure. Therefore, general shear failure, including sliding along a predetermined failure plane, such as a bedding plane, is not likely to occur.

The results of the bearing capacity analyses are summarized in Table 2.5.4-27R. Note that lower-bound material properties were used in Equation 2.5.4-6 and the numerical models explained above. Additionally, the friction angle and unit weight in Equation 2.5.4-6 are the weight-averaged values within the depth of influence below the RB mat. It is anticipated that the mat foundation overlays a zone of disturbed material with D=0.7, to account for disturbed rock mass from blasting and stress relief. The extent of this disturbed zone is unknown and dependent upon the blasting technique used. However, it is unlikely to extend to depths beyond 10 to 15 ft below the foundation level. Conservatively, this zone was assumed to be 25 ft thick below the foundation. At the center of the foundation the remaining layers within the depth of

influence consists of an 89 ft layer of undisturbed Benbolt that overlays 124 ft of Rockdell formation.

The minimum allowable vertical bearing capacity predicted by the U.S. Army Corps of Engineers (USACE), Reference 2.5.4-43, reaches q_a = 76 ksf, which provides a margin of at least nine times the anticipated service load of the reactor building.

Results from the 3D FEM model align with the positive bearing capacity margins computed from Equation 2.5.4-6. In fact, the 3D findings show that by loading the RB mat with three times its anticipated vertical load (FS=3), the materials below the RB's foundation are absent of any form of nonlinear behavior and consequently remain elastic. Figure 2.5.4-43 (left) illustrates the nonlinear state below the RB mat at three times its vertical load. The 3D model reported failure to reach a converged state at six times the anticipated RB's vertical load. As Figure 2.5.4-44 shows, the lack of plastic points below the RB foundation proves that the material remains within the elastic regime; and therefore, significantly high allowable bearing capacity is expected.

For the RB, the results of the stress-strain analyses from the 3D FE model confirmed that the rock under the RB is capable of withstanding significantly high loads and provided reasonable confidence in the values computed from the conventional methods. Therefore, the allowable bearing capacities estimated using Reference 2.5.4-43 (i.e., 76 ksf) is the recommended q_a at this stage (Table 2.5.4-27R).

A parametric approach was used in evaluating the bearing capacity of the structures surrounding the RB, where the bearing capacity for various foundation widths are evaluated. It is important to note that the existing fill and residual soil layer lies between the shallow engineered backfill and rock in the subsurface profile under these surface-founded structures. A shallow foundation system is also considered for these structures (without deep foundations such drilled shafts). The analysis focused solely on the inherent bearing capacity of the shallow foundations resting on a subsurface profile comprised of backfill, existing fill and residual soil, and rock with lower range estimates of mechanical properties. The results show that the bearing capacity increases with the foundation size and slowly reaches a plateau at larger foundation widths (>60 feet). The average allowable net capacity (by considering an FS = 3) obtained assuming lower bound material properties is approximately 2.0 ksf. Maximum and minimum allowable capacities reached 2.3 ksf and 1.6 ksf, respectively. These correspond to foundations of 100 and 10 ft wide.

SAM and SRM results show similar trends to those of the load control counterpart, although with slightly higher values. Under SAM and SRM methodologies, the average allowable capacity reaches 2.4 ksf. Figure 2.5.4-45 illustrates the results from both methodologies.

Figure 2.5.4-46 consolidates the results for the structures. Since these findings correspond to results under plane strain conditions, these need to be affected by the shape factor to incorporate dimensional effects. After this modification, the admissible capacity for the power block structures is $q_a[ksf] = 1.7 \times \left(1 - 0.4\frac{B}{L}\right)$ for B < 40 ft, and $q_a[ksf] = 2.5 \times \left(1 - 0.4\frac{B}{L}\right)$ for B > 60 ft.

Capacities vary linearly for foundation widths between 40 and 60 ft.

A summary of q_a values computed for the various structure foundations at Unit 1 location is provided in Table 2.5.4-27R.

2.5.4.10.1.3 Allowable Bearing Capacity of Concrete

Renumber Equation 2.5.4-9 to Equation 2.5.4-7 in ESPA SSAR Section 2.5.4.10.1.3.

Rename and Replace ESPA SSAR Section 2.5.4.10.1.4 with the following:

2.5.4.10.1.4 Ultimate and Allowable Pseudo Static Bearing Capacity

A pseudo-static approach is followed to evaluate the ultimate seismic capacity q_{uE} at the CRN Site. For the reactor building, q_{uE} is obtained using Soubra's method (Reference 2.5.4-62). The values of pseudo-static bearing capacity factors, $N_{c,E}$,$N_{q,E}$, $N_{\gamma,E}$ are obtained as functions of the horizontal seismic coefficient (K_h) and friction angle. Pseudo-static ultimate capacity is obtained replacing the pseudo-static bearing capacity factors in the bearing capacity equation (i.e., $q_{uE} = 0.5\ \gamma \beta\ N_{\gamma.E} F_{yd} + \gamma D\ N_{q.E} F_{qd} + c\ N_{c.E} F_{cd}$).

Notice that pseudo-static capacity takes credit from cohesion contribution; however, as a conservative measure, a 1/3 reduction factor is applied to the cohesion term in the pseudo-static bearing capacity equation.

For surface-founded structures around the RB, pseudo-static capacities are computed following a load control approach similar to the one explained in Subsection 2.5.4.10.1.1. In the pseudo-static method, the soil mass within the failure surface also experiences a lateral body force. This body force, i.e., gravity force, emulates inertia effects generated by horizontal accelerations within the soil.

The applied lateral forces depend on the magnitude of the horizontal seismic coefficient (K_h). For the RB, K_h and the Peak Ground Acceleration ratio (PGA/g) are assumed equal. The PGA for rock foundation is obtained by averaging the median and the bounding spectral acceleration at 100 Hz from the 5 percent damped horizontal site-specific Foundation Input Response Spectra (FIRS). This acceleration value is found to be 0.55g, which translates into a seismic coefficient of K_h=0.55. At this stage of the analysis, for structures surrounding the RB on the other hand, K_h is assumed to be half the seismic coefficient of the RB. Rounding up, the seismic coefficient for the facilities surrounding the RB becomes K_h = 0.3.

Allowable bearing pseudo-static capacity (q_{aE}) is defined as the ultimate pseudo-static bearing capacity divided by the dynamic factor of safety (FS_E). A safety factor no lower than two is typically required for foundation bearing capacity involving seismic input (Reference 2.5.4-46). The safety factor reduction is consequence of the transient nature of the dynamic load. A FS_E of 2 is applied to each of the methods described above.

Soubra's methodology presents an allowable vertical pseudo-static capacity of 168 ksf for the RB. This value corresponds to a horizontal seismic coefficient of K_h = 0.55. The larger capacity compared to the static counterpart comes from differences between the safety factors and contributions from cohesion. Thus, q_{aE} = 168 ksf is the recommended allowable pseudo-static capacity for the RB foundation.

For the mat foundations of other structures within the footprint of Unit 1, Figure 2.5.4-47 illustrates the distribution of effective plastic strain and the percentage of applied load at the last converged state. In the simulations a series of parametric studies were performed in which for a wide range of foundation widths, all foundations were subjected to a target vertical load of 10 ksf and K_h=0.3. Despite differences in the spatial distribution of the effective plastic bands, foundation widths consistently anticipate maximum load ratios varying between 26 and 34 percent of the prescribed load, returning an average ultimate pseudo-static capacity of 3 ksf. Figure 2.5.4-48 summarizes the vertical load ratios at failure. By applying FS_E=2.0, the average allowable capacity reaches 1.5 ksf. This average capacity needs to be further modified by the corresponding shape factor to consider the impact of the foundation's geometry. Thus, q_{aE} =1.5(1-0.4B/L) ksf is the recommended allowable pseudo-static capacity for the mat foundations of the power block structures. A summary of q_{aE} values computed for the various structure foundations at Unit 1 location is provided in Table 2.5.4-27R.

The results of the bearing capacity analyses show that the rock layers below the SC1 structure, i.e., RB foundation, show significantly high static and dynamic bearing capacity. Other structures within the footprint of Unit 1 layout that are constructed near the final plant grade did not show high bearing capacity due to the presence of the existing fill and residual soil layer in the subsurface profile. It is also noted that the lower range of mechanical properties of existing fill and residual soil were used in the analyses to provide a more conservative evaluation. In order to provide sufficient bearing capacity for these structures, additional measures will be taken to improve the shallow surface soil conditions at the site. Given the relatively shallow depth to the competent bedrock, drilled shafts socketed in unweathered rock (Benbolt) are anticipated to improve the bearing capacity of the surface founded structures. Since the design of these structures is still in progress, the bearing capacity analyses will be re-evaluated and revised at the final design stage.

2.5.4.10.2 Settlement and Heave Analysis

Replace ESPA SSAR Section 2.5.4.10.2 with the following:

Given the deep excavation required for the construction of the RB, an unloading (heave) of the underlying bedrock during construction is expected. Settlement and heave analyses using rock mass properties are evaluated for the RB foundation. Moreover, in addition to the RB, there are several surface-founded structures around the RB shaft for which the settlement is evaluated. Three-dimensional (3D) FE modeling is used by incorporating the subsurface stratigraphy and rock mass properties (as discussed in Subsection 2.5.4.2.4.4) to simulate the subsurface condition and estimate settlement and heave under the structures of Unit 1 at the CRN Site.

2.5.4.10.2.1 Settlement Analysis

Replace ESPA SSAR Section 2.5.4.10.2.1 with the following:

The SC1 structure (RB) at the CRN Site has an embedment depth that is expected not to exceed 115 ft below finished grade; thus, this structure is founded directly on bedrock and settlement, if any, is expected to be small. A foundation contact pressure of 8.4 ksf from the RB is used for the analysis. A 3D finite element model has been developed to evaluate the foundation settlement. The details and results of this analysis are presented in Subsection 2.5.4.13. The 3D model is attempting to simulate the actual field conditions at and around the RB by incorporating the initial state of the subsurface stratigraphy, rock mass properties and rock bedding planes, various interface conditions, potential impact of blasting during excavation, changes due to construction sequences, and applying the structure service loads. The results confirmed that the settlement of the RB foundation remains below 0.05 in. (Table 2.5.4-33R).

The CRN Site ESPA conducted settlement and heave analyses using rock mass properties. Rockmass deformation modulus, E_{rm}, values for combinations of D and GSI (E_{rm} values using the Reference 2.5.4-22 and Reference 2.5.4-23 methods as described in Subsection 2.5.4.2.4.4) were used in the analyses. The Hoek and Diederichs method (Reference 2.5.4-22) incorporates both GSI and D while the Gokceoglu (Reference 2.5.4-23) method incorporates only GSI. This results in three E_{rm} values for each of the upper-bound and lower-bound GSI with D = 0 and D = 0.7 (two are Hoek and Diederichs, Reference 2.5.4-22, and one is Gokceoglu (Reference 2.5.4-23). According to the CRN Site ESPA findings, using these six E_{rm} values leads to six estimations of settlement and heave for the foundation and stratigraphic unit, representing the three E_{rm} calculation methods and the conditions for an undisturbed and a disturbed rock mass. For settlement and heave analyses, the 2013 CRN Site analysis considered each stratigraphic unit within the depth of influence of a respective foundation separately, this is, as a single infinite rock layer below the foundation. Consequently, settlements associated with layers of low stiffness exhibited the larger settlement. Per Table 2.5.4-28R, the estimated total settlements range between 0.01 to 0.28 in.

In the case of the surface founded structures, the settlement analysis in the 3D FE model started with a base model, in which the shallow foundation of the structures rest on a layer of engineered backfill that is underlain by the existing fill and residual soil. The results of the settlement analyses from the base model for the surface founded structures showed that the considered total and differential settlement thresholds were exceeded. It is noted that the lower range of mechanical properties of soil and rock were used in the analyses to provide a more conservative evaluation.

In order to overcome the settlement issue for these surface-founded structures, additional measures will be taken to improve the shallow surface soil conditions at the site. Given the relatively shallow depth to the competent bedrock, drilled shafts socketed in unweathered rock (Benbolt) are anticipated. In the preliminary design of the drilled shaft, the designer considered the consolidating layer (existing fill and residual soil) into account in the down-drag calculations to support the design. Therefore, the need for consolidation analysis is eliminated. The impact of

drilled shafts is evaluated using equivalent uniform properties as discussed in Subsection 2.5.4.13.

2.5.4.10.2.2 Heave Analysis

Renumber Equation 2.5.4-11 to Equation 2.5.4-8 in ESPA SSAR Section 2.5.4.10.2.2.

Replace the second paragraph of ESPA SSAR Section 2.5.4.10.2.2 with the following:

Table 2.5.4-32R shows that total heave ranges from 0.01 in. to 0.36 in. and the largest estimated total heave is less than 0.5 in. The measured heave is likely closer to the heave value given for the larger GSI since the lower heave value represents a disturbed zone (D = 0.7) for the full depth of influence beneath the foundation; in practice, the disturbed zone due to excavation is considerably less than this.

A more detailed computation of the anticipated heave is obtained by means of the 3D FE model mentioned before. Subsection 2.5.4.13 presents and discusses the findings from numerical simulations.

2.5.4.10.3 Lateral Earth Pressure

Renumber Equation 2.5.4-12 to Equation 2.5.4-9 in ESPA SSAR Section 2.5.4.10.3.

Renumber Equation 2.5.4-13 to Equation 2.5.4-10 in ESPA SSAR Section 2.5.4.10.3.

Replace the second paragraph of ESPA SSAR Section 2.5.4.10.3 with the following:

With an embedment depth expected not to exceed 115 ft below final plant grade and assuming the materials behind the walls are in an at-rest condition, the at-rest earth pressure coefficient is used to determine lateral pressure. Reference 2.5.4-14 provides the at-rest lateral earth pressure coefficient:

Replace the last paragraph of ESPA SSAR Section 2.5.4.10.3 with the following:

Evaluation of these components and a full assessment of lateral earth pressure is conducted during the OLA. This evaluation includes finite element modeling using site-specific foundation input response spectra to determine the seismic component of lateral earth pressure.

2.5.4.11 Design Criteria

Replace ESPA SSAR Section 2.5.4.11 with the following:

The criteria summarized below are considered geotechnical criteria. These criteria have been initially addressed in the 2013 CRN Site analysis, they have been re-evaluated and confirmed upon the completion of processing and evaluating the data from the 2023 supplemental site investigation program at the CRN Site and will be evaluated again at the final design stage.

- The liquefaction potential of cohesive residual soils at the CRN Site is evaluated in Subsection 2.5.4.8. RG 1.198 provides that cohesive soils with fines content greater than 30 percent that are either classified as clays or have a PI greater than 30 percent should generally not be considered susceptible to liquefaction. The residual soils are characterized with a fines content of 80 percent and a PI of 40 percent and are thus not considered susceptible to liquefaction. Methods to evaluate the liquefaction potential of fine grained soils (References 2.5.4-41 and 2.5.4-42) confirm this conclusion. The proposed granular backfill, based on the gradation and level of compaction, was also not considered susceptible to liquefaction.
- Bearing capacity and settlement criteria for the selected reactor technology and associated structures have not been finalized by the manufacturer and will be addressed at the final design stage.
- Subsection 2.5.5 discusses the stability of slopes at the site; with the preliminary site grading information established, the presence of any SC1 slopes is not required for the BWRX-300 reactor technology. The PMF analysis assumes a minimum slope of 3:1.

Since the design of the BWRX-300 reactor technology is still in progress, other geotechnical-related criteria that pertain to structural design (such as wall rotation, sliding, and overturning) are addressed at the final design stage.

2.5.4.12 Techniques to Improve Subsurface Conditions

Replace the first paragraph of ESPA SSAR Section 2.5.4.12 with the following:

The presence of karst at the CRN Site is described in Subsection 2.5.1.2.5. Given the RB will be constructed inside a deep vertical shaft, the use of geophysical methods from the surface to evaluate the presence of karst below the elevation of the RB foundation is difficult. Instead, a subsurface investigation using other geophysical methods to evaluate the presence of karst is recommended. A combined survey using ground penetrating radar (GPR) and a multi-frequency electromagnetic (EM) survey to be implemented in the base of the excavation as it progress would be implemented. The goal of this investigation is to detect any potential voids below the foundation level within a certain zone of influence (void zone of influence). The void zone is developed considering the minimum size and location (both area and depth) of a potential void beneath the foundation that does not detrimentally impact the foundation. The density of GPR/EM lines and the number of surveys (every lift, every other lift, etc.) implemented would depend on the depth of the zone of influence and the resolution required to detect potential voids. If anomalies are identified during the geophysical investigation, core drilling will be conducted to validate the anomalies and identify remedial needs. Remediation may include grouting.

Replace the third, fourth and fifth paragraph of ESPA SSAR Section 2.5.4.12 with the following:

Excavation mapping shall be conducted during the entire excavation as described in Reference 2.5.4-38. An instrumentation plan will be developed to monitor lateral and vertical displacement during excavation and construction. Slope inclinometers and horizontal extensometers will be installed to monitor slope movement. Extensometers will be installed to

monitor heave in subsurface materials due to the excavation associated relaxation of the rock mass. Settlement monitors will be installed to monitor the vertical movement during and after construction. Piezometers will be installed to monitor changes in pore pressures during excavation and dewatering, and settlement due to construction of the structures. The RB area is underlain by hard rock, where heave and settlement due to construction activities are expected to be minimal and to take place simultaneously with construction. Any monitoring will be developed and implemented prior to the start of construction.

2.5.4.13 Foundation Assessment Model

Replace ESPA SSAR Section 2.5.4.13 with the following:

A 3D finite element model was developed to simulate the actual subsurface conditions and construction sequences to the extent that is reasonably practical. This numerical model provides insights into different aspects including the settlement and heave, bearing capacity, lateral earth pressure, and hydro-static pressure under the footprint of Unit 1 at the CRN Site. Performing this additional foundation assessment is consistent with the requirements specified in Section 4 of NEDO-33914-A (Reference 2.5.4-57) for performing foundation interface analyses (FIA). All analyses were performed using Three-Dimensional (3-D) Finite Element (FE) modeling in Midas-GTS-NX program.

The subsurface stratigraphy in the 3D model was developed based on the 2013 CRN SMR borings information and general structural geology of the site at Unit 1 location. The service load from the Reactor Building and all surrounding surface-founded structures (e.g. Control, Radwaste, Turbine, and Service Buildings) are modeled in the 3D FE model. The foundation of the Reactor Building is assumed to be 4.0-ft thick mat foundation, the outside diameter of the RB shaft is 36.4 m (119.4 ft), and the vertical shaft the RB is made of 2.0-ft thick composite steel brick. The top of the foundation of the surface founded structures is assumed at the final plant grade, with mat thickness that varies between 1.22 m (4.0 ft) to 2.54 m (8 ft 4 in.), depending on the structure. Figure 2.5.4-27R presents Midas-GTS-NX model layout for Unit 1.

Two cases are evaluated with the 3D model: a base model, and an alternative model (or bounding model). The base model includes a relatively shallow soil profile from the final plant grade to top of rock, which consists of engineered backfill underlain by the existing fill and residual soil layer without any other foundation improvement. After running the simulation of this base model, it was observed that the total and differential settlement of the surface founded structures exceeded the considered thresholds. To limit the settlement, an alternative foundation system with improved soil condition was developed. The improvement is intended to simulate the equivalent stiffness of 36-in-diameter drilled shafts (caissons or drilled piers) that transfer the load from surface-founded structures to unweathered rock. The equivalent stiffness was estimated by performing a series of parametric studies. Therefore, the drilled shafts were not modeled explicitly in the current 3D model. It is noted that because of the relatively large number of drilled shafts, simulating them would significantly increase the computational demands of the 3D model and since their design at this stage is considered preliminary, the computation of such model would not be flexible to any potential design changes of the drilled shaft before the design is finalized.

The Support of Excavation (SOE) system is assumed to maintain a stable excavation and limit the lateral displacement of the surrounding shallow soil and weathered rock masses during construction of the deeply embedded vertical shaft at CRN Site. This system includes temporary excavation support (anchored soldier pile wall with lagging) and compression rings. Figure 2.5.4-28R shows a conceptual schematic of the RB vertical shaft, shoring system, and caissons in a cross-section view. Figure 2.5.4-29R presents the Finite Element 3D model mesh for Unit 1 (note that the drilled shafts were modeled using equivalent stiffness properties).

To account for the disturbance in rock caused by blasting during the rock mass excavation, a 25-ft thick zone of disturbed rock mass was assumed around the RB shaft perimeter and below the bottom of excavation. The disturbed rock mass properties for the Benbolt formation were calculated using the lower bound GSI equivalent properties and a Disturbance Factor (D) of 0.7.

An initial groundwater level at El. 800 ft was assumed coinciding with the existing ground surface. A long-term design groundwater level at El. 814.5 ft coinciding with the final plant grade elevation was assumed as a final condition after all surface building construction. Temporary dewatering is required to maintain a dry excavation; therefore, it was assumed dewatering progresses with excavation and the impact of changes in the hydrostatic pressure during and after construction is evaluated. The RB shaft excavation will be performed in lifts. Prior to excavation of each lift, the water level inside the excavation will be lowered to the base of each lift, while maintaining the water elevation outside the excavation at the global initial groundwater level of El. 800 ft. A seepage analysis was then performed to estimate the pore pressures which are used as an input for the following stress-deformation excavation construction stage.

Figure 2.5.4-30R presents the excavation stages assumed for the construction of the RB vertical shaft. Figure 2.5.4-31 presents the compression rings (conceptual layout) modeled for the construction of the RB vertical shaft. Figure 2.5.4-32 presents the disturbed rock mass zone surrounding the Reactor Building vertical shaft.

The interaction between the diaphragm wall and surrounding soil/rock was modeled via interface elements in Midas-GTS-NX. Regarding the material properties of the interface, the strength reduction factor of the interface (R_{inter} = 0.7) was used to relate the interface stiffness and strength to the adjacent soil/rock stiffness and strength properties. The rock mass was modeled using an elasto-plastic Mohr-Coulomb model, in which the discontinuities within each rock mass are accounted for through the GSI values specified for each geologic unit (and subsequently the equivalent Mohr-Coulomb failure parameters φ' and c’ are used). The lower bound estimates of rock mass properties were used in this model. Moreover, discontinuities along stratigraphic boundaries (such as the contact between the Benbolt and Rockdell formations) were simulated using interface elements (R_{inter} = 0.7) with reduced stiffness compared to those of the adjacent rock formations to represent potential discontinuities and fracture zones between the geologic units.

2.5.4.13.1 Foundation Assessment Results

The 3D FE model provided a large amount of data on the variation of stresses and deformations in soil and rock throughout the several construction stages. Some of the post-processed outputs

from the 3D model are presented in this subsection. Figure 2.5.4-27R shows the locations and cross sections where the results are extracted.

Figure 2.5.4-33 presents the lateral pressures acting on the vertical walls in the RB shaft after loading Reactor Building and surrounding surface-founded structures to the design loads. The lateral pressures were extracted from the normal stresses acting on the interface elements from the alternative 3D model that uses the equivalent properties for soil and weathered rock (i.e., with the impact of drilled shafts). In addition, the RB vertical shaft experiences lateral hydrostatic pressure over its full depth. Total and effective lateral stresses acting on the RB vertical shaft walls in the Benbolt formation are very similar from all directions. However, in the subsurface soils, the lateral pressures from the Turbine and Radwaste buildings sides are higher compared to the Control and Service buildings' sides due to the higher building loads of the Turbine and Radwaste buildings and the bigger footprint of the Turbine building.

Figure 2.5.4-34 presents the lateral deformations corresponding to the loading condition in Figure 2.5.4-33. Lateral deformations of the vertical shaft walls in the subsurface soils and Benbolt formation are very similar from all directions. The lateral deformations from the Turbine and Radwaste buildings sides are higher compared to the Control and Service buildings sides due to the higher building loads of the Turbine and Radwaste buildings and the bigger footprint of the Turbine building. These results confirm that stable conditions in rock during the excavations and construction sequences (as they were modeled in this 3D FE model) can be accomplished.

Bearing pressure under the foundations, in particular under the RB foundation, at the end of final construction stage is another important output from the 3D simulations. Figure 2.5.4-35 presents the distribution of total bearing pressure beneath all foundations by post processing the outputs of the 3D model that uses equivalent properties for soil and weathered rock (i.e., with the impact of drilled shafts). The values of the pressures at the locations of cross sections A-A', B-B', and C-C', were extracted and plotted in Figure 2.5.4-36 and Figure 2.5.4-37.

The other important output of the 3D FE model is estimates of total and differential settlement for the foundations of the RB and surface founded structures under the service loads. As anticipated, the stiff unweathered rock under the RB foundation did not deform noticeably under the applied service load. The estimated settlement was less than 0.05 inches for the RB foundation in both the base case (without the impact of drilled shafts) and alternative model (bounding model with the impact of drilled shafts) models. On the other hand, the differential settlements computed in the base case model for the surface founded structures exceeded the considered threshold of 0.5 inches in 50 ft.

The amount of unloading from excavation versus the amount of reloading from the new structures results in a net decrease in bearing pressure. The calculated settlement and heave values presented in Table 2.5.4-33R are small compared to reported values in ESPA (Table 2.5.4-31R and Table 2.5.4-32R) and differences in magnitude are due to the different analytical approaches available to calculate settlement and heave. The settlement is largely attributed to recompression of the material as opposed to new elastic or consolidation settlement. The estimated heave and settlement are expected to be instantaneous, occurring during and shortly after construction. No long-term settlement is expected after construction.

Table 2.5.4-33R shows the estimated settlement in the Benbolt formation at depth 115 ft below finished grade (at base of Reactor Building foundation mat) after loading the Reactor Building with the design loads. Additionally, Table 2.5.4-33R shows the estimated heave in the Benbolt formation at depth 119.5 ft below finished grade (at base of Reactor Building foundation mud-mat) from the excavation sequence. Figure 2.5.4-38 through Figure 2.5.4-40 show plot of the estimated Benbolt settlement distribution beneath the Reactor Building foundation mat. Figure 2.5.4-49 shows plot of the estimated Benbolt heave distribution beneath the Reactor Building foundation mud-mat.

The Foundation Interface Analysis is performed for Unit 1 at Location A only. It considers lower-bound GSI values and a D value of 0.7 for the disturbed zone due to excavation activities. The total estimated settlement in the Benbolt formation at depth 115 ft below finished grade (at base of Reactor Building foundation mat) after loading the Reactor Building with the design loads is less than 0.05 in. The total estimated heave in the Benbolt formation at depth 119.5 ft below finished grade (at base of Reactor Building foundation mud-mat) from the excavation sequence is less than 0.022 in. The estimated settlement and heave values from the Foundation Interface Analysis are smaller and comparable to the values obtained from the analytical methods presented in Subsection 2.5.4.1.1.1 and Subsection 2.5.4.1.1.2 for Location A and lower-bound GSI values, respectively.

Figure 2.5.4-38 presents the settlement distribution computed for all foundations within the footprint of Unit 1 by post processing the outputs of the alternative 3D model that uses equivalent properties for soil and weathered rock (i.e., with the impact of drilled shafts). The settlement values at the locations of cross sections A-A', B-B' and C-C' (illustrated on Figure 2.5.4-38) were extracted and plotted in Figure 2.5.4-39 and Figure 2.5.4-40. The settlement values computed in the alternative model are smaller than the corresponding values from the base case model. Additionally, the differential settlements resulted from the alternative 3D model (with the equivalent properties for soil and weathered rock, i.e., with the impact of drilled shafts) were all below the considered threshold of 0.5 inches in 50 ft. It is anticipated that stiff drilled shaft elements will most likely provide smaller settlement values; therefore, the improvement introduced by the drilled shaft will provide stable conditions.

The impact of potentially undetected karst features under or around the RB foundation on the stability of the SC1 structure was evaluated in detail by considering the BWRX-300 technology initial general layout (Reference 2.5.4-65) at CRN Site. According to the subsurface data from the 2013 and 2023 CRN Site investigations, approximately 99 percent of the cavities observed in the borings are significantly smaller than 11 ft and the inferred height and the maximum observed cavity height did not exceed 17 ft. Moreover, cavity development in the CRN Site areas is generally limited to the most markedly weathered zone immediately below ground surface, to depths less than 100 ft; in fact, about 75 percent of the reported cavities in the borings from the 2013 and 2023 CRN Site investigations had been observed at depths less than 55 ft.

The selection of the size and location of the karst cavities and disturbed rock mass zone was in part informed by the 2013 CRN site investigation data (Reference 2.5.4-64). It is noted that in order to simulate the actual condition at the CRN Site, additional 3D FE models were developed to investigate the impact of undetected cavities on the stability of the new proposed system. The

size of the cavities in the FE models are compatible with the height of the cavities detected and observed in the 2013 CRN site investigation program. Consistent with the previous cavity evaluation, two spherical karst features (cavities) were considered to examine the stability of the BWRX-300 RB deeply embedded vertical shaft and surrounding structures. One of the karst features, modeled as a 15-ft (diameter) cavity, is located 5 feet beneath the centerline of the RB mat foundation and the second one, with similar dimensions, is located 5 feet adjacent to the RB vertical shaft and 2 feet below the top of the unweathered rock below the Radwaste Building (heaviest surface structure). To account for the rock disturbance and stress release from blasting activities during excavation, a 25 feet thick zone of disturbed rock mass (D=0.7) is assumed around the shaft perimeter and 25 feet below the RB mat foundation base. The two cavities are embedded in these weakened zones. Additionally, the lower range mechanical properties have been assigned to the soil and rock mass in these simulations.

The results of the 3D FE models were evaluated in the context of the impact of the potential cavities on the deformations and stress distribution in the domain at different stages of construction and loading. Similar to the previous results, these simulations showed that the postulated cavities did not have any meaningful impact on the stability of the foundation. This study was based on the first generation layout (Reference 2.5.4-65); however, at the final design stage, the 3D finite element model will be re-evaluated and updated based on any changes on structures in terms of location, dimension, elevation of foundations, and subgrade material properties.

2.5.5 Stability of Slopes

Replace ESPA SSAR Section 2.5.5 with the following (Addresses ESP COL Action Item 2.5-17):

The information presented in this subsection is based on the results of the site-specific subsurface investigation performed at the Clinch River Nuclear Site, which is described in Subsection 2.5.4. Note that the detailed data collected from this 2013 and the 2023 CRN Site investigations are contained in Reference 2.5.5-1, Reference 2.5.5-4, and Reference 2.5.5-5, respectively.

The Clinch River Nuclear Site is located along the Clinch River arm of the Watts Bar Reservoir within the City of Oak Ridge, Tennessee. The topography in this area consists of a series of northeast to southwest trending alternating ridges and valleys. During previous site grading at the Clinch River Property, as described in Subsection 2.5.4.1, portions of the ridges were excavated and some of the valleys were filled resulting in a gently sloping topography within the power block area. To the west of the power block area, an excavation approximately 35 ft deep remains from the previous site grading. Several ridges are located east of the power block area.

As described in Subsection 2.5.4.1, the existing ground surface at and around the power block area at the time of the 2013 CRN Site investigation program is generally gently sloping downward from northwest to southeast, ranging from approximately Elevation 855 to 780 ft North American Vertical Datum of 1988 (NAVD88) (Reference 2.5.5-1). Note that all references to elevations given in this subsection are to NAVD88. The power block finish grade elevation is at 814.5 ft.

Details of the proposed site grading are developed for the BWRX-300 technology. The planned finished grade elevation is at elevation of 814.5 ft, and a flat table-top site with no SC1 slopes is proposed (Reference 2.5.5-2).

2.5.5.1 Slope Characteristics

The planned finished grade elevation of the power block area is set at 814.5 ft. The power block configuration and site grading do not include any permanent slopes.

During construction, a temporary excavation cut slope will be made in the power block area to construct foundations. This excavation will be made in soil, weathered rock, and hard rock. The excavation will include vertical faces for the Reactor Building shaft. The excavation will be backfilled, and no permanent slopes will remain within close proximity (the shortest distance between permanent slope and SC1 structure is greater than 900 ft, Reference 2.5.5-3) to the SC1 structure after construction in the power block area.

Groundwater conditions in the power block area, including seepage and high and low groundwater levels, are discussed in Subsection 2.4.12.

2.5.5.2 Design Criteria and Analyses

No permanent SC1 slopes are identified. Construction excavation cut slopes will be required in the power block area for construction of the foundations. Soil and rock will be removed and replaced with compacted granular backfill and lean concrete, respectively. The final design of the excavation, including excavation support and slope stabilization details, is developed in the OLA. The construction excavation cut slopes will be temporary since they are for the construction period only. The excavation will be backfilled and none of these slopes will remain after construction in the power block area (Reference 2.5.5-3).

2.5.5.3 Results of the Investigation

As described in Subsection 2.5.4, a detailed subsurface investigation encompassing the power block area was conducted and included material characterization, foundation analysis, and rock mass characterization. These data will be used for design of the foundation excavation cut slopes.

2.5.5.4 Properties of Borrow Material

Information related to backfill and borrow material for SC1 backfill is provided in Subsection 2.5.4.5.

CHAPTER 3 DESIGN OF STRUCTURES, SYSTEMS, AND COMPONENTS

This chapter identifies and describes the principal design and analysis of the BWRX-300 structures, systems, and components (SSCs). The appendices to this chapter provide supporting information for:

- SSC safety class, seismic category, and Quality Group classification, Appendix 3A
- Design and analysis of seismic structures, Appendices 3B through 3H
- Computer programs used for design and analysis of SSCs, Appendices 3I through 3M
- Aircraft impact assessment, Appendix 3N

3.1 Compliance with U.S. Nuclear Regulatory Commission General Design Criteria

This section contains an evaluation of the GEH Boiling Water Reactor (BWR), BWRX-300 standard plant design, analyses, procurement, and construction requirements for compliance with 10 Code of Federal Regulations (CFR) 50, Appendix A, “General Design Criteria for Nuclear Power Plants.”

The BWRX-300 design incorporates passive safety features that are designed to safely shut down the reactor and maintain it in a safe shutdown condition without reliance on Alternating Current (AC) power, external cooling water, or operator action for Anticipated Operational Occurrences (AOO) and Design Basis Accident (DBA) Postulated Initiating Events (PIE). The motive power for the passive safety systems is supplied by stored energy sources such as Direct Current (DC) power, compressed gas, springs, or gravity. In addition, the BWRX-300 design is provided with a complement of highly reliable systems that reduce the challenge to the passive safety systems and provide the capability for extending the safe shutdown period.

Because the General Design Criteria (GDC) are not technology-neutral and are predicated on legacy design, some GDC have been substituted with Principal Design Criteria (PDC) in accordance with 10 CFR 50.34(a)(3)(i) and (ii). Technology neutral guidance from Appendix A, “Advanced Reactor Design Criteria,” to Regulatory Guide (RG) 1.232, “Guidance for Developing Principal Design Criteria for Non-Light-Water-Reactors,” is used to inform the development of the BWRX-300 PDCs.

Table 3.1-1 provides references to the other Preliminary Safety Analysis Report (PSAR) sections where additional design and analysis information is discussed. GDC 1-5 are omitted from Table 3.1-1 because they have plant-wide applicability.

3.1.1 Group I – Overall Requirements

3.1.1.1 GDC 1 – Quality Standards and Records

GDC 1 Statement

Structures, systems, and components important to safety shall be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety functions to be performed. Where generally recognized codes and standards are used, they shall be identified

and evaluated to determine their applicability, adequacy, and sufficiency and shall be supplemented or modified as necessary to assure a quality product in keeping with the required safety function. A quality assurance program shall be established and implemented in order to provide adequate assurance that these structures, systems, and components will satisfactorily perform their safety functions. Appropriate records of the design, fabrication, erection, and testing of structures, systems, and components important to safety shall be maintained by or under the control of the nuclear power unit licensee throughout the life of the unit.

Evaluation Against GDC 1

Safety Class 1 (SC1) Structures, Systems, and Components (SSCs), and their Safety Category 1 functions, are subject to the GEH Quality Assurance (QA) program, which satisfies the requirements of 10 CFR 50, Appendix B, “Quality Assurance Criteria for Nuclear Power Plants and Fuel Reprocessing Plants” and American Society of Mechanical Engineers (ASME) NQA-1-2015, “Quality Assurance Requirements, for Nuclear Facility Applications,” (Reference 3.1-7) with the exceptions and clarifications noted in RG 1.28, “Quality Assurance Program Criteria (Design and Construction).” Quality controls for non-SC1 SSCs that are risk-significant are consistent with “U. NONSAFETY-RELATED SSC QUALITY CONTROLS” of NUREG-0800, Standard Review Plan (SRP), Section 17.5. Subsection 17.4.5 describes Risk-Significant Criteria established for SSCs.

Documents are maintained to demonstrate that the requirements of the QA program are satisfied. This documentation shows that appropriate codes, standards, and regulatory requirements are identified, correct materials are specified, correct procedures are utilized, qualified personnel are provided, and the finished parts and components meet the applicable specifications. These records are maintained and retrievable for the life of the operating licenses.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 1 are met.

3.1.1.2 GDC 2 – Design Bases for Protection Against Natural Phenomena

GDC 2 Statement

Structures, systems, and components important to safety shall be designed to withstand the effects of natural phenomena such as earthquakes, tornadoes, hurricanes, floods, tsunami, and seiches without loss of capability to perform their safety functions. The design bases for these structures, systems, and components shall reflect: (1) Appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area, with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated, (2) appropriate combinations of the effects of normal and accident conditions with the effects of the natural phenomena and (3) the importance of the safety functions to be performed.

Evaluation Against GDC 2

SSCs classified as SC1 are designed to retain capability to perform their Safety Category 1 functions during and after design basis natural phenomena events. SSCs whose failure during a seismic event could prevent a Seismic Category I SSC from performing its Safety Category 1 functions are designed to ensure such failure does not occur. For non-SC1 SSCs:

- Structures housing radiological waste materials are designed for external hazard protection in accordance with RG 1.143, “Design Guidance for Radioactive Waste Management Structures, Systems, and Components Installed in Light-Water-Cooled Nuclear Power Plants.”
- The Main Control Room (MCR) and associated egress route between the MCR and Secondary Control Room (SCR) are protected such that human occupants of those areas are not caused incapacitating physical harm as a result of any design basis natural phenomena event.
- Equipment that is qualified and located to remain functional during and following design basis external hazards is provided to support display of a suitable inventory of indications that allow confirmation of Fundamental Safety Function (FSF) performance and status of physical barriers to release.
- Equipment determined to be risk-significant based on external hazard-specific Probabilistic Safety Assessment (PSA) modeling, such as Seismic PSA, is provided with additional protection and/or designated for qualification to survive the hazard conditions.

Selection of design basis natural phenomena events reflects consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area, with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated. Selection of design basis natural phenomena events also reflect appropriate combinations of the effects of normal and accident conditions with the effects of the natural phenomena.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 2 are met.

3.1.1.3 GDC 3 – Fire Protection

GDC 3 Statement

Structures, systems, and components important to safety shall be designed and located to minimize, consistent with other safety requirements, the probability and effect of fires and explosions. Noncombustible and heat-resistant materials shall be used wherever practical throughout the unit, particularly in locations such as the containment and control room. Fire detection and fighting systems of appropriate capacity and capability shall be provided and designed to minimize the adverse effects of fires on structures, systems, and components important to safety. Firefighting systems shall be designed to assure that their rupture or inadvertent operation does not significantly impair the safety capability of these structures, systems, and components.

Evaluation Against GDC 3

The following design features minimize the probability of a fire or assure adequate protection in the event of a fire:

- Probability of fires occurring in the plant is minimized by the following measures:
  - Noncombustible and heat resistant materials such as metal cabinets, metal wireways, high melting point insulation, and flame-resistant markers for identification are used wherever practicable.
  - Electrical cabling is suitably rated and protected, and cable tray loading is designed to avoid unacceptable internal heat buildup.
- Redundant divisions of SC1 equipment and fire safe shutdown equipment are in separate fire areas or fire zones as needed to ensure one path to achieve fire safe shutdown is available (except the inerted containment).
- Electrical cabling supporting SC1 equipment and fire safe shutdown equipment is routed with separation to ensure one path to achieve fire safe shutdown is available (except the inerted containment).
- SC1 and fire safe shutdown SSCs are designed and located to minimize, consistent with other safety requirements, the probability and effect of fires and explosions.
- The FPS is provided with appropriate detection, capacity, and capability to minimize impact of fires on SC1 and fire safe shutdown SSCs.
- Location and method of fire suppression are selected such that the impacts of rupture or inadvertent operation do not prevent the performance of a Safety Category 1 function.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 3 are met.

3.1.1.4 GDC 4 – Environmental and Dynamic Effects Design Bases

GDC 4 Statement

Structures, systems, and components important to safety shall be designed to accommodate the effects of and to be compatible with the environmental conditions associated with normal operation, maintenance, testing, and postulated accidents, including loss-of-coolant accidents. These structures, systems, and components shall be appropriately protected against dynamic effects, including the effects of missiles, pipe whipping, and discharging fluids, that may result from equipment failures and from events and conditions outside the nuclear power unit. However, dynamic effects associated with postulated pipe ruptures in nuclear power units may be excluded from the design basis when analyses reviewed and approved by the Commission demonstrate that the probability of fluid system piping rupture is extremely low under conditions consistent with the design basis for the piping.

Evaluation Against GDC 4

SC1 SSCs are designed to be compatible with environmental conditions associated with normal operation, maintenance, testing, and postulated pipe failure accidents including Loss-of-Coolant Accidents (LOCA). Design requirements specify the duration that SC1 SSCs must survive the

environmental conditions following a LOCA. The Safety Class 2 (SC2) and Safety Class 3 (SC3) SSCs that mitigate PIEs are confirmed to be compatible with the environmental and dynamic effects present during the event scenarios where these functions are credited. Additionally, the failure of non-SC1 equipment due to environmental and dynamic effects will not impair SC1 equipment.

For piping in containment penetration areas, the probability of fluid system piping rupture is demonstrated to be extremely low under conditions consistent with the design basis for the piping, such that line breaks do not need to be postulated for the purpose of the evaluation of potential dynamic effects. Accordingly, SC1 SSCs do not require protection against dynamic effects, including the effects of pipe whipping, jet impingement, and blast wave and blowdown loads that may result from piping failure. The effects of missiles originating from inside or outside the plant are also considered.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 4 are met.

3.1.1.5 GDC 5 – Sharing of Structures, Systems, and Components

GDC 5 Statement

Structures, systems, and components important to safety shall not be shared among nuclear power units unless it can be shown that such sharing will not significantly impair their ability to perform their safety functions, including, in the event of an accident in one unit, an orderly shutdown and cooldown of the remaining units.

Evaluation Against GDC 5

CRN-1 is a single unit and does not share any SSCs with other nuclear power units.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 5 are met.

3.1.2 Group II – Protection by Multiple Fission Product Barriers

3.1.2.1 GDC 10 – Reactor Design

GDC 10 Statement

The reactor core and associated coolant, control, and protection systems shall be designed with appropriate margin to assure that specified acceptable fuel design limits are not exceeded during any condition of normal operation, including the effects of anticipated operational occurrences.

Evaluation Against GDC 10

The “reactor core” includes both the mechanical and fuel design aspects of fuel assemblies and internal/supporting core structures. Design measures are applied to the reactor core design to assure margin to Specified Acceptable Fuel Design Limits (SAFDL) during normal operating conditions and AOO event sequences. Examples of such design measures include the following:

- The mechanical design is based on conservative application of stress limits, Operating Experience (OPEX), and experimental test results.
- The reactor core is designed to maintain integrity considering a complete range of power levels, including normal operation and AOO event sequence conditions.
- The reactor core is sized with sufficient heat transfer area and coolant flow to assure that SAFDLs are not exceeded.
- Mechanical analyses confirm that Reactor Pressure Vessel (RPV) internals remain intact during normal operation, AOO event sequence conditions and beyond with appropriate margins (using ASME Boiler and Pressure Vessel Code (BPVC) Service Level approach). These structures are assumed to stay intact in the evaluations that ensure SAFDLs are not exceeded.
- Evaluations of normal operation and AOO event sequence conditions are performed for each fuel design and fuel cycle based on the design of the reactor core and associated coolant, control, and protection systems to confirm SAFDLs are not exceeded.

“Associated coolant systems” include the passive Reactor Coolant Pressure Boundary (RCPB) equipment, RPV internal components including the core support structure, passive Isolation Condenser System (ICS) equipment, and connected process systems such as main steam and feedwater. In this context, passive means vessels, piping, heat exchanger tubing, and other equipment, and example design and analysis measures include the following:

- The mechanical design of RCPB components, reactor internals, and connected coolant systems is based on conservative application of stress limits, OPEX, and experimental test results.
- These associated coolant systems are assumed to stay intact and perform as designed in the evaluations that ensure SAFDLs are not exceeded because they are designed in accordance with the appropriate ASME BPVC requirements for the applicable service level.

“Associated control systems” include the control, electrical, mechanical and measurement elements that support control during normal operations, with example measures such as:

- Reactor power, pressure, and level control to ensure normal operation is consistent with the normal operation conditions assumed in SAFDL evaluations. Level and pressure control are included in Deterministic Safety Analysis (DSA) of AOO event sequence conditions to demonstrate SAFDLs are not exceeded.

"Associated protection systems" include the control, electrical, mechanical and measurement elements that support mitigation during AOO event sequence conditions. The protective functions performed by these elements are typically Safety Category 3 functions. Example measures include the following:

- Protective function setpoints are selected to ensure the FSFs are performed and SAFDLs are not exceeded during AOO event sequences.
- Equipment performing protective functions is tested to confirm that its performance attributes are consistent with the performance modelled in evaluation of SAFDLs.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 10 are met.

Additional information discussing the compliance approach to GDC 10 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.2.2 GDC 11 – Reactor Inherent Protection

GDC 11 Statement

The reactor core and associated coolant systems shall be designed so that in the power operating range the net effect of the prompt inherent nuclear feedback characteristics tends to compensate for a rapid increase in reactivity.

Evaluation Against GDC 11

The New Fuel Licensing requirements established in NEDE-24011-P-A, "General Electric Standard Application for Reactor Fuel (GESTAR II)," (Reference 3.1-8), stipulate that the net prompt reactivity feedback due to prompt heating of the moderator and fuel shall be negative for a reactivity insertion event originating from any operating condition. GNF2 has been evaluated generically and affirmed to satisfy this requirement and the results are summarized in NEDC-33270P, "GNF2 Advantage Generic Compliance with NEDE-24011-P-A (GESTAR II)," (Reference 3.1-9). The GNF2 application to the BWRX-300 with the N-lattice has separately been confirmed to satisfy this requirement.

Additionally, NEDE-24011-P-A establishes requirements governing other nuclear dynamic parameters pertaining to reactor safety.

Together, compliance with these requirements assures the inherent reactivity feedback mechanisms are consistent with reactor safety. GNF2 has been evaluated, generically, to satisfy all requirements governing nuclear dynamic parameters, including the prompt power coefficient.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 11 are met.

Additional information discussing the compliance approach to GDC 11 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.2.3 GDC 12 – Suppression of Reactor Power Oscillations

GDC 12 Statement

The reactor core and associated coolant, control, and protection systems shall be designed to assure that power oscillations which can result in conditions exceeding specified acceptable fuel design limits are not possible or can be reliably and readily detected and suppressed.

Evaluation Against GDC 12

The BWRX-300 design addresses stability utilizing an RPV chimney that increases natural circulation core flow so that a margin to instability that could challenge SAFDLs is maintained for all modes of operation. In accordance with GDC 12, it is required that the power response to a sudden insertion of reactivity (typically a pressurization event) results in a coupled power and core flow response such that SAFDLs are not exceeded.

The BWRX-300 maintains a coupled power and flow response such that any initial perturbation that does not cause an immediate scram, decays quickly to steady state even at the limiting point of the cycle. Also, the relatively small core of the BWRX-300 is a design measure which causes it not to be susceptible to regional modes of oscillation. Therefore, a special stability detection and trip system (i.e., a “protection system”) is not required. The natural circulation driving head provided by the BWRX-300 chimney along with the core orifice design causes core flow and power perturbations to be naturally damped.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 12 are met.

Additional information discussing the compliance approach to GDC 12 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.2.4 GDC 13 – Instrumentation and Control

GDC 13 Statement

Instrumentation shall be provided to monitor variables and systems over their anticipated ranges for normal operation, for anticipated operational occurrences, and for accident conditions as appropriate to assure adequate safety, including those variables and systems that can affect the fission process, the integrity of the reactor core, the reactor coolant pressure boundary, and the containment and its associated systems. Appropriate controls shall be provided to maintain these variables and systems within prescribed operating ranges.

Evaluation Against GDC 13

Instrumentation capable of monitoring important parameters across the anticipated ranges for normal operation, AOO event sequences, and accident conditions are provided by the mechanical systems that are controlled and monitored by the DCIS. The instruments monitor system variables in the reactor core, RCPB, containment and supporting systems. Normal and

off-normal operating ranges are defined to support process control during normal operation and the automatic initiation of safety functions and/or accident monitoring in the event of AOO event sequences or DBA event sequences.

Instruments are classified in accordance with the highest safety category function they support and qualified to operate under the conditions in which their functions are required to be performed.

Safety Category 1 and Safety Category 3 functions are performed by independent and diverse SC1 and SC3 Instrumentation and Control (I&C) systems, respectively, to maintain the specified variables within prescribed operating ranges through normal control or, when required, by automatic safety actuations to assure adequate safety. Diversity is provided to mitigate the risks of common cause failure, and redundancy is provided to meet reliability and availability requirements. The I&C systems also display the monitored parameters during normal operation and for accident monitoring.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 13 are met.

Additional information discussing the compliance approach to GDC 13 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.2.5 GDC 14 – Reactor Coolant Pressure Boundary

GDC 14 Statement

The reactor coolant pressure boundary shall be designed, fabricated, erected, and tested so as to have an extremely low probability of abnormal leakage, of rapidly propagating failure, and of gross rupture.

Evaluation Against GDC 14

The piping and equipment within the RCPB (as defined in 10 CFR 50.2) are designed, fabricated, erected, and tested in accordance with the requirements in 10 CFR 50.55a, Codes and Standards, providing a high degree of integrity throughout the plant lifetime. Piping and equipment within the RCPB are classified as Quality Group A or B, as appropriate. The RCPB is protected from overpressure by ICS. The design requirements and codes and standards applied to Quality Group A and B components ensure high safety function integrity.

To minimize the possibility of brittle fracture within the RCPB, the fracture toughness properties and the operating temperature of ferritic materials are controlled to ensure adequate toughness. Materials are impact tested in accordance with ASME BPVC, Section III, where applicable. Where RCPB piping penetrates the containment, the fracture toughness temperature requirements of the RCPB materials apply.

Piping and equipment within the RCPB are assembled and erected by welding unless applicable codes permit flanged or threaded joints. Welding procedures are employed that produce complete fusion welds that are free of unacceptable defects. All welding procedures, welders, and welding machine operators used in producing pressure containing welds are qualified in

accordance with the requirements of the ASME BPVC, Section IX for materials welded. Qualifications records, including the results of procedure and performance qualification tests and identification symbols assigned to each welder are maintained.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 14 are met.

Additional information discussing the compliance approach to GDC 14 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.2.6 GDC 15 – Reactor Coolant System Design

GDC 15 Statement

The reactor coolant system and associated auxiliary, control, and protection systems shall be designed with sufficient margin to assure that the design conditions of the reactor coolant pressure boundary are not exceeded during any condition of normal operation, including anticipated operational occurrences.

Evaluation Against GDC 15

The Reactor Coolant System (RCS) includes the SC1 portion of the Nuclear Boiler System (NBS) and the SC1 portion of the Condensate and Feedwater Heating System (CFS). The RCS extends to and includes the outermost Containment Isolation Valve (CIV) in the Main Steam (MS) and Feedwater (FW) piping. The RCPB includes the pressure retaining components of the RCS and connected systems up to and including their respective outboard CIVs.

The RCS for a BWR includes the RPV, the Nuclear Boiler System (NBS), which includes the Main Steam sub-system to the outboard CIVs, and a portion of the Feedwater system to the outboard CIVs. The RCPB includes the RCS plus ICS and portions of the Control Rod Drive (CRD) and Reactor Water Cleanup (CUW) systems.

Safety Category 3 functions, implemented in at least SC3 equipment, are provided to automatically initiate hydraulic scram and pressure control functions (e.g., turbine bypass valves, or ICS pressure control) so that the design conditions of the RCPB are not exceeded during AOO event sequences. If monitored parameters exceed their predetermined setpoints, the Safety Category 3 functions automatically respond to maintain the parameters within their allowable design limits.

Overpressure protection for AOO event sequences is provided in accordance with ASME BPVC, Section III, NB-7120(b) and (c) by Safety Category 3 functions and ICS, respectively. These ensure that the acceptance criteria for each component in the protected system are met including 1) the overpressure does not exceed 1.1 times design pressure for the expected system pressure transient condition, and 2) the calculated stress intensity and other design limitations for Service Level C are not exceeded for the unexpected system excess pressure transient condition.

Design measures are also employed in the design of the RCPB, such that it accommodates pressure conditions expected for normal operations, AOO event sequences, DBA event sequences, and Design Extension Condition (DEC) event sequences. This means significant margin for normal operation and AOO event sequences. For example, the mechanical design of RCPB components is based on conservative application of ASME BPVC stress limits, OPEX, and qualification test results.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 15 are met.

Additional information discussing the compliance approach to GDC 15 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.2.7 GDC 16 – Containment Design

GDC 16 Statement

Reactor containment and associated systems shall be provided to establish an essentially leak-tight barrier against the uncontrolled release of radioactivity to the environment and to assure that the containment design conditions important to safety are not exceeded for as long as postulated accident conditions require.

Evaluation Against GDC 16

An essentially leak-tight Steel-Plate Composite Containment Vessel (SCCV) encloses the RPV, including the majority of the RCPB and other branch connections for the NBS, and includes containment penetrations with essentially leak-tight isolation design features including CIVs, blind flanges, hatches, and electrical penetrations. A steel head encloses the opening in the top of the SCCV for servicing and refueling the RPV. The major piping systems (main steam, feedwater, ICS, and other systems) are located in the upper SCCV region. The lower SCCV region encloses the lower portion of the RPV and encloses the Fine Motion Control Rod Drives (FMCRD) and associated piping and other systems as well as providing maintenance space below the RPV. Temperature and pressure conditions inside the SCCV are controlled and maintained below acceptance criteria following an accident for at least 72 hours by RPV decay heat removal using the ICS and condensation on the SCCV walls and with containment heat removal using the Passive Containment Cooling System (PCCS).

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 16 are met.

Additional information discussing the compliance approach to GDC 16 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.2.8 PDC 17 – Electric Power Systems

PDC 17 Statement

An electric power system shall be provided when required to permit functioning of systems and components that are relied upon to perform FSFs in the event of a loss of AC power. The electric power systems shall have sufficient capacity and capability to ensure that (1) the design limits for

the specified acceptable fuel design limits are not exceeded as a result of anticipated operational occurrences and (2) safety functions that rely on electric power are maintained in the event of DBAs.

Evaluation Against PDC 17

The electric power provisions in PDC 17 apply to GDC 18, 34, 35, 38, 41, and 44:

- Electric Power for AOOs and SAFDLs

  Safety Category 3 functions that protect SAFDLs are provided power by the SC3 DC power system. The SC3 DC power system has the capacity and capability to provide power to SC3 DC loads, such as DCIS.

- Electric Power for DBAs

  The BWRX-300 design assures that the FSFs are maintained for DBAs. The electric power system is the SC1 Emergency Power System for monitoring and actuating SC1 passive systems, such as emergency core cooling provided by the ICS. All passive SC1 systems for DBAs are actuated by SC1 Distributed Control and Information System (DCIS) control systems that are supplied power from the Emergency Power System 72-hour DC emergency batteries.

The SC1 Emergency Power System and DCIS have sufficient independence, redundancy, and testability to perform their Safety Category 1 functions and meet the single failure criterion.

Accordingly, the requirements of PDC 17 are met.

Additional information discussing the compliance approach to PDC 17 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.2.9 GDC 18 – Inspection and Testing of Electric Power Systems

GDC 18 Statement

Electric power systems important to safety shall be designed to permit appropriate periodic inspection and testing of important areas and features, such as wiring, insulation, connections, and switchboards, to assess the continuity of the systems and the condition of their components. The systems shall be designed with a capability to test periodically (1) the operability and functional performance of the components of the systems, such as onsite power sources, relays, switches, and buses, and (2) the operability of the systems as a whole and, under conditions as close to design as practical, the full operation sequence that brings the systems into operation, including operation of applicable portions of the protection system, and the transfer of power among the nuclear power unit, the offsite power system, and the onsite power system.

Evaluation Against GDC 18

All SC1 loads are normally supplied directly through DC to AC inverters. Capability is provided for testing each battery, rectifier, battery charger, and inverter without disrupting power to the SC1 loads.

Design of the SC1 power system provides testability in accordance with the requirements of GDC 18.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 18 are met.

Additional information discussing the compliance approach to GDC 18 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.2.10 PDC 19 – Control Room

PDC 19 Statement

A control room shall be provided from which actions can be taken to operate the nuclear power unit safely under normal conditions and anticipated operational occurrences, and to maintain it in a safe condition during design basis accidents. Adequate radiation protection shall be provided to permit access and occupancy of the control room during design basis accidents without personnel receiving radiation exposures in excess of 5 rem total effective dose equivalent as defined in 10 CFR 50.2.

Equipment at appropriate locations outside the control room shall be provided with a design capability for safe shutdown of the reactor, including necessary instrumentation and controls to maintain the unit in a safe shutdown condition.

Evaluation Against PDC 19

PDC 19 requires the capability to operate the plant under normal conditions, AOOs, and DBAs while providing adequate radiation protection, state-of-the-art human factors principles, and control room habitability such as heating, ventilation, cooling, and lighting. Additionally, PDC 19 clarifies the radiation protection requirements for control room inhabitants consistent with current industry practice.

BWRX-300 design demonstrates adequate radiation protection to permit access and occupancy of the MCR or SCR so that personnel do not receive radiation exposures in excess of 5 rem Total Effective Dose Equivalent (TEDE) for DBAs.

The BWRX-300 design includes means outside the MCR for operators to place and maintain the reactor in a safe condition in the event of a control room evacuation. For the BWRX-300 reactor design, the establishment of PDC 19 to require “safe shutdown” capability outside the MCR is supported and consistent with U.S. Nuclear Regulatory Commission (USNRC) guidance, such as SECY-94-084, “Policy and Technical issues Associated with the Regulatory Treatment of Non-Safety Systems in Passive Plant Designs,” which applies to passive residual heat removal systems and RG 1.189, “Fire Protection for Nuclear Power Plants,” regarding fire in the MCR. In

the event of an MCR evacuation, the reactor is tripped, and decay heat removal and containment isolation are initiated prior to operators evacuating the MCR, provided that the control capabilities remain operable. Operators can also place the reactor in safe shutdown from the Seismic Category I SCR within the Reactor Building (RB).

Accordingly, the BWRX-300 control room design provides a means from which actions can be taken to operate the nuclear power unit safely under normal conditions and to maintain it in a safe condition during DBAs.

Accordingly, the requirements of PDC 19 are met.

Additional information discussing the compliance with PDC 19 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.3 Group III – Protection and Reactivity Control Systems

3.1.3.1 GDC 20 – Protection System Functions

GDC 20 Statement

The protection system shall be designed (1) to initiate automatically the operation of appropriate systems including the reactivity control systems, to assure that specified acceptable fuel design limits are not exceeded as a result of anticipated operational occurrences and (2) to sense accident conditions and to initiate the operation of systems and components important to safety.

Evaluation Against GDC 20

NEDC-33934P, “BWRX-300 Safety Strategy,” (Reference 3.1-1), discusses the applicability of the “protection system” described in GDC 20 to the BWRX-300 design.

The protection functions are organized into layers of Defense Lines (DL). Analyses demonstrating the capability of the different DLs to protect the fission product barriers (i.e., fuel cladding, reactor coolant pressure boundary, and containment pressure boundary) to the applicable acceptance criteria are layered as well. The different DLs are implemented and analyzed for each AOO and DBA PIE.

The BWRX-300 layered safety analyses include a Baseline Deterministic Safety Analysis (BL-DSA) and a Conservative Deterministic Safety Analysis (CN-DSA). The BL-DSA is performed to demonstrate the capability of Safety Category 3 functions to mitigate AOO PIEs to ensure SAFDLs are not exceeded. The CN-DSA is performed to demonstrate that Safety Category 1 functions alone can mitigate the effects of the same AOO PIEs with the added assumption that Safety Category 3 functions fail to respond. The CN-DSA also demonstrates that Safety Category 1 functions can mitigate the effects of DBA PIEs. The CN-DSA demonstrates, for each AOO and DBA PIE, that the Safety Category 1 functions independently assure the integrity of the RCPB, the capability to shut down the reactor and maintain it in a safe shutdown condition, and the capability to prevent or mitigate the consequences of accidents that could result in potential offsite exposure.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 20 are met.

Additional information discussing the compliance approach to GDC 20 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.3.2 GDC 21 – Protection System Reliability and Testability

GDC 21 Statement

The protection system shall be designed for high functional reliability and inservice testability commensurate with the safety functions to be performed. Redundancy and independence designed into the protection system shall be sufficient to assure that (1) no single failure results in loss of the protection function and (2) removal from service of any component or channel does not result in loss of the required minimum redundancy unless the acceptable reliability of operation of the protection system can be otherwise demonstrated. The protection system shall be designed to permit periodic testing of its functioning when the reactor is in operation, including a capability to test channels independently to determine failures and losses of redundancy that may have occurred.

Evaluation Against GDC 21

The systems implementing Safety Category 1 protection functions are designed with redundancy and independence between redundant divisions to fulfill the single-failure criterion. No single component failure, intentional bypass maintenance operation, calibration operation, or test to verify operational availability, impairs the ability of the systems to perform their Safety Category 1 functions. Independence between redundant divisions prevents failures occurring in one division from impairing the ability of the other divisions to function correctly.

With one division inoperable, the required minimum redundancy is temporarily lost. Acceptable reliability of operation is established by limiting the time such a condition can exist through Technical Specifications.

Design features, such as self-testing routines in digital equipment, that permit inservice testing are included in the design and the Safety Category 1 functions can be tested during reactor operation.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 21 are met.

Additional information discussing the compliance approach to GDC 21 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.3.3 GDC 22 – Protection System Independence

GDC 22 Statement

The protection system shall be designed to assure that the effects of natural phenomena, and of normal operating, maintenance, testing, and postulated accident conditions on redundant channels do not result in loss of the protection function or shall be demonstrated to be acceptable

on some other defined basis. Design techniques, such as functional diversity or diversity in component design and principles of operation, shall be used to the extent practical to prevent loss of the protection function.

Evaluation Against GDC 22

Safety Category 1 functions are implemented with independence between redundant equipment such that the effects of natural phenomena, and of normal operation, maintenance, testing, and postulated accident conditions do not result in loss of the minimum redundancy required for successful performance of Safety Category 1 functions. Redundant SC1 sensors are electrically and physically separated, and only circuits of the same division are run in the same raceway. Signals required to cross divisional boundaries to implement the 2 out of 3 voting logic use fiber optic communication pathways to maintain electrical isolation between divisions. SC1 equipment is also seismically and environmentally qualified to function in the expected environments resulting from natural phenomena events or accidents.

The SC1 I&C systems are designed to permit maintenance and diagnostic work while the reactor is operating, without restricting the plant operation or hindering the output of safety functions. Operational system testing can be performed using independent input for each division. When a monitored variable supporting a Safety Category 1 function exceeds its scram trip point, it is sensed by three independent sensors, each located in a separate instrumentation channel.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 22 are met.

Additional information discussing the compliance approach to GDC 22 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.3.4 GDC 23 – Protection System Failure Modes

GDC 23 Statement

The protection system shall be designed to fail into a safe state or into a state demonstrated to be acceptable on some other defined basis if conditions such as disconnection of the system, loss of energy (e.g., electric power, instrument air), or postulated adverse environments (e.g., extreme heat or cold, fire, pressure, steam, water, and radiation) are experienced.

Evaluation Against GDC 23

The systems implementing Safety Category 1 protection functions are designed to fail into a safe state (or a state demonstrated to be acceptable on another basis) if conditions such as disconnection of the system, loss of energy, or postulated adverse environments are experienced. Use of independent divisions allows the system to sustain any single divisional failure without preventing redundant divisions from initiating the Safety Category 1 protection functions.

The environmental conditions in which the instrumentation and equipment of the SC1 systems must operate are considered in establishing the component specifications. Instrumentation specifications are based on the worst expected ambient conditions in which the instruments must operate.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 23 are met.

Additional information discussing the compliance approach to GDC 23 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.3.5 GDC 24 – Separation of Protection and Control Systems

GDC 24 Statement

The protection system shall be separated from control systems to the extent that failure of any single control system component or channel, or failure or removal from service of any single protection system component or channel which is common to the control and protection systems leaves intact a system satisfying all reliability, redundancy, and independence requirements of the protection system. Interconnection of the protection and control systems shall be limited so as to assure that safety is not significantly impaired.

Evaluation Against GDC 24

Safety Category 1 functions are implemented separately from Safety Category 3 functions to the extent that either of the following conditions leaves intact a group of equipment satisfying all reliability and independence requirements necessary to assure performance of the FSFs for design basis events:

- Failure of any single component performing Safety Category 1 functions
- Removal from service of any single component that supports both Safety Category 3 and Safety Category 1 functions

Interconnections between equipment performing Safety Category 3 functions and Safety Category 1 functions are limited such that one category of functions remains available in the presence of any credible single failure, or credible Common Cause Failure (CCF), postulated to affect mitigation capabilities of either category. Credible means those considered within the “Design Basis Event (DBE)” analysis set of BL-DSA and CN-DSA.

Electrical isolation, data communication isolation and functional independence are implemented to prevent faults in a lower classified system from propagating to a higher classified system.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 24 are met.

Additional information discussing the compliance approach to GDC 24 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.3.6 GDC 25 – Protection System Requirements for Reactivity Control Malfunctions

GDC 25 Statement

The protection system shall be designed to assure that specified acceptable fuel design limits are not exceeded for any single malfunction of the reactivity control systems, such as accidental withdrawal (not ejection or dropout) of control rods.

Evaluation Against GDC 25

Safety Category 3 protection system functions assure that SAFDLs are not exceeded for reactivity control malfunctions. To minimize the likelihood of a rod withdrawal error, the rod control system incorporates redundancy to limit the effect of single failures. If there is a malfunction of the rod control system that results in a rod withdrawal error, a Safety Category 3 rod movement block function is initiated to terminate rod movement.

As a design measure, redundancy is employed throughout the reactivity control systems such that:

- No single equipment failure leads to inadvertent movement of more than one control rod, and
- Vulnerabilities to single equipment failures which could cause inadvertent movement of a single control rod are minimized.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 25 are met.

Additional information discussing the compliance approach to GDC 25 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.3.7 GDC 26 – Reactivity Control System Redundancy and Capability

Criterion 26 Statement

Two independent reactivity control systems of different design principles shall be provided. One of these systems shall use control rods, preferably including a positive means for inserting the rods, and shall be capable of reliably controlling reactivity changes to assure that under conditions of normal operation, including anticipated operational occurrences, and with appropriate margin for malfunctions such as stuck rods, specified acceptable fuel design limits are not exceeded. The second reactivity control system shall be capable of reliably controlling the rate of reactivity changes resulting from planned, normal power changes (including xenon burnout) to assure acceptable fuel design limits are not exceeded. One of the systems shall be capable of holding the reactor core subcritical under cold conditions.

Evaluation Against GDC 26

Two independent reactivity control systems utilizing different design principles are provided. The normal method of reactivity control employs control rod assemblies. A Boron Injection System (BIS) is also provided.

Reactivity control methods utilized during normal operation and AOOs employ control rod assemblies. The CRD system is designed such that no single active failure of a CRD component or supporting system function will prevent a reactor scram. Positive insertion means of controlling reactivity include: 1) the hydraulic scram control rod insertion function using the Hydraulic Control Units (HCUs) and control rods, and 2) the motor-driven control rod positioning function for normal power maneuvering which includes a separate motor-driven control rod run-in insertion function using the Fine Motion Control Rod Drives (FMCRDs) and control rods.

The CRD system is capable of maintaining the reactor core subcritical under cold conditions, even if the highest worth pair of control rods associated with an HCU is assumed to be in the fully withdrawn position. This shutdown capability of the CRD system is made possible by designing the core configuration to ensure the reactor core is held subcritical under cold conditions.

The means of normal reactivity control use a common set of control rods; however, the hydraulic scram function is not precluded by the operation or malfunction of the motor-driven FMCRD control rod positioning or run-in design features. The FMCRDs motor-driven function is independent from the hydraulic-driven function such that the use of a common set of control rods to control normal power operations does not introduce any additional challenges or failure mechanisms to the scram function. The FMCRDs and associated control rods are located separately and physically independent in the reactor core (i.e., each control rod is physically separated from each other by fuel assemblies). There are no identified mechanical interactions between control rods that would affect more than one control rod pair at a time.

The Boron Injection System (BIS) provided in the BWRX-300 is used as a Defense-in-Depth measure to reduce reactor power to achieve and then maintain the reactor core subcritical under cold conditions, even if all control rods remain fully withdrawn. The BIS assures reactor shutdown by mixing a neutron absorber with the reactor coolant.

Accordingly, the requirements of GDC 26 are met. Additional information discussing the compliance approach to GDC 26 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.3.8 GDC 27 – Combined Reactivity Control Systems Capability

GDC 27 Statement

The reactivity control systems shall be designed to have a combined capability, in conjunction with poison addition by the emergency core cooling system, of reliably controlling reactivity changes to assure that under postulated accident conditions and with appropriate margin for stuck rods the capability to cool the core is maintained.

Evaluation Against GDC 27

The control rods are capable of reliably controlling reactivity changes to assure that under postulated accident conditions and with appropriate margin for stuck rods, the capability to shut down the reactor (and cool the core) is maintained. Positive automatic insertion of the control rods (i.e., scram) is provided by the HCU accumulators in response to design basis accidents

(DBAs) that require emergency core cooling system operation (i.e., initiation of reactor isolation and the isolation condenser system (ICS)). Successful scram and initiation of reactor isolation and the ICS is shown to both achieve and maintain safe shutdown of the reactor without the possibility of a return to criticality, even with the unlikely occurrence of two stuck rods or a single failure of an HCU accumulator during scram. GDC 27 is satisfied for the BWRX-300 without the injection of soluble boron.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 27 are met.

Additional information discussing the compliance approach to GDC 27 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.3.9 GDC 28 – Reactivity Limits

GDC 28 Statement

The reactivity control systems shall be designed with appropriate limits on the potential amount and rate of reactivity increase to assure that the effects of postulated reactivity accidents can neither (1) result in damage to the reactor coolant pressure boundary greater than limited local yielding nor (2) sufficiently disturb the core, its support structures or other reactor pressure vessel internals to impair significantly the capability to cool the core. These postulated reactivity accidents shall include consideration of rod ejection (unless prevented by positive means), rod dropout, steam line rupture, changes in reactor coolant temperature and pressure, and cold-water addition.

Evaluation Against GDC 28

The combined features of the CRD system and the rod control system incorporate appropriate limits on the potential amount and rate of reactivity increase. The fine motion capability of the FMCRD allows reactivity additions from rod withdrawal to be finely controlled by the rod control system. Normal rod movement and the rod withdrawal rate are limited by the rod control system and follow sequences assigned by the core designers to operate the core within thermal limits. The rod control system controls rod patterns and provides control rod blocks to limit the rate and amount of reactivity addition for control rod movement. The BWRX-300 FMCRD and control rod guide tube designs prevent rod drop and rod ejection events through positive design means. Control rod drop is prevented by use of a bayonet style coupling between the FMCRD and the control rod, CRD mechanism latches that maintain the control rod inserted after a scram, and FMCRD separation switches that detect a control rod that has become separated from the FMCRD ball nut. Upon detection of separation from the ball nut, the rod control system prevents further outward rod motion of the ball nut by enforcing a withdrawal block. Control rod ejection is prevented by physical constraints including a flange at the top of the control rod guide tube that is above the core plate to prevent guide tube ejection and the FMCRD connection to the control rod guide tube via a bayonet coupling. The FMCRD includes an electro-mechanical brake that further prevents inadvertent rod withdrawal by engaging to prevent rod motion if the control system is not commanding rod motion. For the case of a scram line break, the FMCRD includes an internal ball check valve which reduces the chances of rapid rod withdrawal. The ball check valve functions as SC1 component because it serves as a RCPB function and prevents reverse

flow from the scram inlet port caused by a break of the scram line, thus preventing the loss of pressure from the underside of the hollow piston and the generation of loads on the drive that would tend to cause a rod withdrawal and associated reactivity insertion.

The safety analyses evaluate the postulated reactivity accidents, as well as abnormal operational transients, in detail. Analyses are included for steam line break, changes in reactor coolant temperature and pressure, and cold water addition. The initial conditions, assumptions, calculational models, sequences of events, and anticipated results of each postulated occurrence are covered in detail. The results of these analyses indicate that none of the postulated reactivity transients or accidents results in damage to the RPV internals, so that the capability to cool the core is not impaired.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 28 are met.

Additional information discussing the compliance approach to GDC 28 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.3.10 GDC 29 – Protection Against Anticipated Operational Occurrences

GDC 29 Statement

The protection and reactivity control systems shall be designed to assure an extremely high probability of accomplishing their safety functions in the event of anticipated operational occurrences.

Evaluation Against GDC 29

The combination of Safety Category 3 protection functions and independent Safety Category 1 protection functions, arranged in DLs providing layered protection against AOO initiating events, results in extremely high functional reliability for performance of the FSFs, including reactivity control.

A thorough program of inservice testing and surveillance maintains an extremely high reliability of protection function responses to AOO initiating events over the plant lifetime.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 29 are met.

Additional information discussing the compliance approach to GDC 29 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.4 Group IV – Fluid Systems

3.1.4.1 GDC 30 – Quality of Reactor Coolant Pressure Boundary

GDC 30 Statement

Components which are part of the reactor coolant pressure boundary shall be designed, fabricated, erected, and tested to the highest quality standards practical. Means shall be provided for detecting and, to the extent practical, identifying the location of the source of reactor coolant leakage.

Evaluation Against GDC 30

The components of the RCPB, including the RPV isolation valves, CIVs, ICS, and portions of the CRD and CUW systems, and the overpressure protection equipment (ICS and ICS actuation valves) are designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety functions to be performed in accordance with generally recognized codes and standards, and under an approved QA program with approved control of records, as required by 10 CFR 50.55a and 10 CFR 50, Appendix A, GDC 1. In addition, means are provided to detect and identify the location of the source of reactor coolant leakage for components of the RCPB. The BWRX-300 design includes only unidentified leakage that is potentially from the RCS. As identified leakage is not defined, there is no leakage separation.

Leakage detection is provided to detect, annunciate, and, in some cases, isolate the RCPB from potentially hazardous leaks before predetermined limits are exceeded. Leaks/breaks may be detected by temperature and pressure changes, increased frequency of sump pump operation, increased airborne radioactivity, changes in flow rates in process lines, or changes in reactor water level.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 30 are met.

Additional information discussing the compliance approach to GDC 30 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.4.2 GDC 31 – Fracture Prevention of Reactor Coolant Pressure Boundary

GDC 31 Statement

The reactor coolant pressure boundary shall be designed with sufficient margin to assure that when stressed under operating, maintenance, testing, and postulated accident conditions (1) the boundary behaves in a nonbrittle manner and (2) the probability of rapidly propagating fracture is minimized. The design shall reflect consideration of service temperatures and other conditions of the boundary material under operating, maintenance, testing, and postulated accident conditions and the uncertainties in determining (1) material properties, (2) the effects of irradiation on material properties, (3) residual, steady-state and transient stresses, and (4) size of flaws.

Evaluation Against GDC 31

Brittle fracture control of pressure-retaining ferritic materials is provided to ensure protection against non-ductile fracture. To minimize the possibility of brittle fracture failure of the RPV, the RPV is designed to meet the requirements of ASME BPVC, Section III.

The reactor assembly design provides an annular space from the outermost fuel assemblies to the inner surface of the RPV that serves to attenuate the fast neutron flux incident upon the RPV wall. This annular volume contains the core shroud and reactor coolant. Assuming plant operation at rated power and 100% availability over the plant life, the cumulative neutron fluence at the inner surface of the RPV causes a slight shift in the transition temperature. Expected shifts in transition temperature during design life as a result of environmental conditions, such as neutron flux, are considered in the design. Operational limitations ensure that Nil-Ductility Transition Temperature (NDTT) shifts are accounted for in the reactor operation.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 31 are met.

Additional information discussing the compliance approach to GDC 31 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.4.3 GDC 32 – Inspection of Reactor Coolant Pressure Boundary

GDC 32 Statement

Components which are part of the reactor coolant pressure boundary shall be designed to permit (1) periodic inspection and testing of important areas and features to assess their structural and leaktight integrity, and (2) an appropriate material surveillance program for the reactor pressure vessel.

Evaluation Against GDC 32

The RPV design includes provisions for inservice inspection. Access to the RPV is provided by removable panels in the insulation. These openings provide access for examination of the RPV and its appurtenances. Removable insulation is provided on the NBS piping and valves extending out to and including the outermost containment isolation valve. Inspection of the RCPB, which includes the ICS, is in accordance with ASME BPVC, Section XI.

Material surveillance samples are located within the RPV.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 32 are met.

Additional information discussing the compliance approach to GDC 32 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.4.4 GDC 33 – Reactor Coolant Makeup

GDC 33 Statement

A system to supply reactor coolant makeup for protection against small breaks in the reactor coolant pressure boundary shall be provided. The system safety function shall be to assure that specified acceptable fuel design limits are not exceeded as a result of reactor coolant loss due to leakage from the reactor coolant pressure boundary and rupture of small piping or other small components which are part of the boundary. The system shall be designed to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished using the piping, pumps, and valves used to maintain coolant inventory during normal reactor operation.

Evaluation Against GDC 33

GDC 33 applies to small leaks in the RCPB that are smaller than the double-ended rupture of an instrument line (e.g., leakage from flanges or cracks in piping or other components), and which do not exceed the capability of the SC3 high-pressure CRD system used as normal reactor coolant makeup during power operations. The maximum allowed leakage rate for continuing power operation is stipulated in the plant TSs. Automatic reactor scram and automatic actuation of the ICS are not anticipated for most of these small leaks because the normal means of makeup from the high-pressure CRD system is sufficient and feedwater maintains the level in the normal operating range. These small leaks, which do not exceed the capability of the high-pressure CRD system, are evaluated using SAFDLs rather than the BWRX-300 acceptance criteria in response to a LOCA.

The high-pressure CRD system pumps can operate using either onsite AC power (assuming offsite power is not available) from the SC3 SDGs or offsite AC power (assuming onsite power is not available).

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 33 are met.

Additional information discussing the compliance approach to GDC 33 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.4.5 GDC 34 – Residual Heat Removal

GDC 34 Statement

A system to remove residual heat shall be provided. The system safety function shall be to transfer fission product decay heat and other residual heat from the reactor core at a rate such that specified acceptable fuel design limits and the design conditions of the reactor coolant pressure boundary are not exceeded.

Suitable redundancy in components and features, and suitable interconnections, leak detection, and isolation capabilities shall be provided to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished, assuming a single failure.

Evaluation Against GDC 34

The SC1 ICS provides the necessary residual heat removal capability for ensuring the SAFDLs are met and RCPB design conditions are not exceeded.

Residual heat removal is performed passively by the ICS system. Neither offsite nor onsite power supplies are utilized in performance of the function.

Three trains of ICS are provided, such that a single failure of any one train does not prevent successful performance of the residual heat removal function.

During refueling, when ICS is unavailable, SC3 active systems are employed to remove decay heat. In case the active systems are lost, the decay heat from the fuel in the RPV can be removed by the UHS.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 34 are met.

Additional information discussing the compliance approach to GDC 34 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.4.6 GDC 35 – Emergency Core Cooling

GDC 35 Statement

A system to provide abundant emergency core cooling shall be provided. The system safety function shall be to transfer heat from the reactor core following any loss of reactor coolant at a rate such that (1) fuel and clad damage that could interfere with continued effective core cooling is prevented and (2) clad metal-water reaction is limited to negligible amounts.

Suitable redundancy in components and features, and suitable interconnections, leak detection, isolation, and containment capabilities shall be provided to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished, assuming a single failure.

Evaluation Against GDC 35

The combined design features of the ICS and RPV isolation valves meet the definition of an Emergency Core Cooling System (ECCS) as described in 10 CFR 50.46(a)(1)(i) that has a calculated cooling performance following postulated LOCAs in compliance with the BWRX-300 acceptance criteria in response to a LOCA, which bound the acceptance criteria set forth in 10 CFR 50.46(b). In addition, the ICS and RPV isolation valves are effective as an ECCS for

breaks in pipes in the RCPB up to and including a break equivalent in size to the double-ended rupture of the largest pipe in the RCS in compliance with the definition of a LOCA in 10 CFR 50.46(c)(1). The ICS has the capability to provide more than sufficient emergency core cooling, which is assured for breaks in pipes in the RCPB up to and including a break equivalent in size to the double ended rupture of the largest pipe in the RCS through the use of the RPV isolation valves for LOCA break sizes greater than 19 millimeters (0.75 inch) diameter.

The BWRX-300 acceptance criteria in response to a LOCA is that reactor water level is maintained at or above the Top of Active Fuel (TAF) or fuel cladding temperature is maintained within normal operating temperature range, such that the performance of the ICS and RPV isolation valves is sufficient to ensure that (1) fuel and clad damage that could interfere with continued effective core cooling is prevented and (2) clad metal-water reaction is limited to negligible amounts.

The ICS design includes features that provide redundancy in components and functions. The worst-case single failure can only affect one ICS train, and their design function can be accomplished with the remaining ICS trains. The ICS is a passive system only requiring condensate return valves to open to place the system in operation. No offsite power is required for operation of the ICS condensate return valve actuators, controls, and actuation systems, and no onsite or offsite power is required after the initial actuation of the ICS condensate return valves. The condensate return valves fail open on loss of all power. Diversity of the ICS automatic actuation valves and automatic actuation signals is provided to ensure that single active failures do not prevent an ICS train from being placed into service. The heat capacity of the Isolation Condenser (IC) heat exchangers and the opening times for the ICS condensate return valves are selected to assure that the BWRX-300 acceptance criteria in response to a LOCA, which bound the acceptance criteria of 10 CFR 50.46(b), are met.

The RPV isolation valve design includes design features that provide redundancy in components and features, including isolation capability, because the worst-case single failure can only affect one RPV isolation valve in each RPV connection, and their design function can be accomplished with the remaining RPV isolation valve in each RPV connection. No offsite power is required for operation of the RPV isolation valve actuators, controls, and actuation systems, and no onsite or offsite power is required after the initial actuation of the RPV isolation valves. Diversity of the RPV isolation valves automatic actuation signals is provided. The isolation times of the RPV isolation valves are selected to assure that the BWRX-300 acceptance criteria in response to a LOCA, which bound the acceptance criteria of 10 CFR 50.46(b), are met.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 35 are met.

Additional information discussing the compliance approach to GDC 35 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.4.7 GDC 36 – Inspection of Emergency Core Cooling System

GDC 36 Statement

The emergency core cooling system shall be designed to permit appropriate periodic inspection of important components, such as spray rings in the reactor pressure vessel, water injection nozzles, and piping, to assure the integrity and capability of the system.

Evaluation Against GDC 36

The ICS and the RPV isolation valve, i.e., Reactor Isolation Valves (RIV), which provide the ECCS function, are designed to permit appropriate periodic inspection of important components, such as piping and valves, to ensure integrity and capability of the ECCS.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 36 are met.

Additional information discussing the compliance approach to GDC 36 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.4.8 GDC 37 – Testing of Emergency Core Cooling System

GDC 37 Statement

The emergency core cooling system shall be designed to permit appropriate periodic pressure and functional testing to assure (1) the structural and leaktight integrity of its components, (2) the operability and performance of the active components of the system, and (3) the operability of the system as a whole and, under conditions as close to design as practical, the performance of the full operational sequence that brings the system into operation, including operation of applicable portions of the protection system, the transfer between normal and emergency power sources, and the operation of the associated cooling water system.

Evaluation Against GDC 37

The ICS and RIVs, which provide the ECCS function, are designed for periodic pressure and functional testing to assure (1) the structural and leaktight integrity of these components, (2) the operability and performance of components which change state to place the ECCS function into operation, and (3) the operability of the systems as a whole.

The Safety Category 1 ICS initiation functions are implemented to allow for periodic testing of the operational sequences that bring the ICS cooling trains into operation, as required by plant TSs.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 37 are met.

Additional information discussing the compliance approach to GDC 37 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.4.9 GDC 38 – Containment Heat Removal

GDC 38 Statement

A system to remove heat from the reactor containment shall be provided. The system safety function shall be to reduce rapidly, consistent with the functioning of other associated systems, the containment pressure and temperature following any loss-of-coolant accident and maintain them at acceptably low levels.

Suitable redundancy in components and features, and suitable interconnections, leak detection, isolation, and containment capabilities shall be provided to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished, assuming a single failure.

Evaluation Against GDC 38

Containment peak pressure and temperature are limited by condensation on containment walls and RPV heat removal by the ICS as well as containment heat removal by the PCCS by natural convection and condensation. The PCCS reduces containment peak pressure rapidly for a large break LOCA, which is the limiting BWRX-300 DBA event sequence. Heat is rejected to the equipment pool and reactor cavity pool above containment by natural circulation using PCCS piping that penetrates the containment. Unisolated small breaks are not limiting for containment peak pressure or temperature. Small breaks less than or equal to 19 millimeters (0.75 inch) do not need to be isolated. These breaks are mitigated by the elevated placement of the small nozzles on the RPV assembly compared to TAF, containment size and the IC heat exchanger size, which helps to depressurize the RPV such that the RPV pressure and containment pressure equalize, and the inventory loss is limited. The PCCS does not require electrical power to operate, and the ICS operation only requires one-time actuation using onsite SC1 battery-backed DC power. Additionally, the ICS fails to an in-service state upon loss of all electrical power.

The PCCS does not have a high duty function for long-term containment cooling as most of the decay heat is removed by the ICS. Three independent redundant trains of PCCS are included in the design to provide a high degree of reliability. For RPV isolation events, containment pressure and temperature are limited by condensation on containment walls and containment heat removal by the PCCS and by RPV decay heat removal by the ICS.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 38 are met.

Additional information discussing the compliance approach to GDC 38 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.4.10 GDC 39 – Inspection of Containment Heat Removal System

GDC 39 Statement

The containment heat removal system shall be designed to permit appropriate periodic inspection of important components, such as the torus, sumps, spray nozzles, and piping to assure the integrity and capability of the system.

Evaluation Against GDC 39

The PCCS is designed, fabricated, erected, inspected, and tested in accordance with ASME BPVC, Section III, Subsections NCA and NCD (for Class 2 components) to permit preservice baseline and inservice inspections per ASME BPVC, Section XI, Subsection IWC, as applicable.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 39 are met.

Additional information discussing the compliance approach to GDC 39 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.4.11 GDC 40 – Testing of Containment Heat Removal System

GDC 40 Statement

The containment heat removal system shall be designed to permit appropriate periodic pressure and functional testing to assure (1) the structural and leaktight integrity of its components, (2) the operability and performance of the active components of the system, and (3) the operability of the system as a whole, and under conditions as close to the design as practical the performance of the full operational sequence that brings the system into operation, including operation of applicable portions of the protection system, the transfer between normal and emergency power sources, and the operation of the associated cooling water system.

Evaluation Against GDC 40

The PCCS accomplishes the containment heat removal function during a large break LOCA. The PCCS forms a closed system inside containment. The PCCS is designed to be periodically pressure tested as part of the Inservice Inspection (ISI) Program required by ASME BPVC, Section XI, Subsection IWC to demonstrate structural and leak-tight integrity. The PCCS piping can be pressure and leak tested during maintenance or inservice inspection using various non-destructive methods.

Functional and operability testing of PCCS components is performed as required by the ASME OM Code and 10 CFR 50, Appendix J. System performance is established analytically for the range of in-containment environmental conditions following a LOCA.

The components of the PCCS are designed with sufficient margin to assure that these requirements for periodic pressure and functional testing during normal operations and emergency events are met. The operation of the PCCS does not require offsite electric power system operation.

The PCCS heat removal function is based on natural circulation and heat removal from condensation, which is analyzed as part of plant design. PCCS operability and performance are ensured by the physical arrangement of the PCCS piping and verified by periodic pressure testing and verification of an open flow path through the system.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 40 are met.

Additional information discussing the compliance approach to GDC 40 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.4.12 GDC 41 – Containment Atmosphere Cleanup

GDC 41 Statement

Systems to control fission products, hydrogen, oxygen, and other substances which may be released into the reactor containment shall be provided as necessary to reduce, consistent with the functioning of other associated systems, the concentration and quality of fission products released to the environment following postulated accidents, and to control the concentration of hydrogen or oxygen and other substances in the containment atmosphere following postulated accidents to assure that containment integrity is maintained.

Each system shall have suitable redundancy in components and features, and suitable interconnections, leak detection, isolation, and containment capabilities to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) its safety function can be accomplished, assuming a single failure.

Evaluation Against GDC 41

The BWRX-300 containment is maintained nitrogen-inerted by the Containment Inerting System (CIS). Fission products, hydrogen, oxygen, and other substances released from the reactor are contained within the low-leakage containment. Because the containment is an inert nitrogen environment, the containment integrity is maintained without employing any further combustible gas control system. Containment leakage after an accident is limited such that the dose guidelines of 10 CFR 50.34(a)(1)(ii)(D) are not exceeded. The BWRX-300 containment is subterranean with underwater pools in the upper RB. As a result, containment leakage pathways to the environment are limited.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 41 are met.

Additional information discussing the compliance approach to GDC 41 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.4.13 GDC 42 – Inspection of Containment Atmosphere Cleanup Systems

GDC 42 Statement

The containment atmosphere cleanup systems shall be designed to permit appropriate periodic inspection of important components, such as filter frames, ducts, and piping to assure the integrity and capability of the systems.

Evaluation Against GDC 42

The CIS inerts the containment atmosphere for plant operation and subsequently exhausts the containment atmosphere to the Heating, Ventilation, and Cooling System (HVS) when the containment is de-inerted. All CIS components are outside containment, accessible for visual inspection during normal plant operation at power, and available for inservice inspection during all normal plant states to assure integrity and functionality of components.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 42 are met.

Additional information discussing the compliance approach to GDC 42 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.4.14 GDC 43 – Testing of Containment Atmosphere Cleanup Systems

GDC 43 Statement

The containment atmosphere cleanup systems shall be designed to permit appropriate periodic pressure and functional testing to assure (1) the structural and leaktight integrity of its components, (2) the operability and performance of the active components of the systems such as fans, filters, dampers, pumps, and valves and (3) the operability of the systems as a whole and, under conditions as close to design as practical, the performance of the full operational sequence that brings the systems into operation, including operation of applicable portions of the protection system, the transfer between normal and emergency power sources, and the operation of associated systems.

Evaluation Against GDC 43

The CIS inerts the containment atmosphere for plant operation and subsequently exhausts the containment atmosphere to the HVS during refueling. The CIS is designed to accommodate preservice testing, pressure testing, and functional testing to ensure the system performs its intended functions.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 43 are met.

Additional information discussing the compliance approach to GDC 43 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.4.15 GDC 44 – Cooling Water

GDC 44 Statement

A system to transfer heat from structures, systems, and components important to safety, to an ultimate heat sink shall be provided. The system safety function shall be to transfer the combined heat load of these structures, systems, and components under normal operating and accident conditions.

Suitable redundancy in components and features, and suitable interconnections, leak detection, and isolation capabilities shall be provided to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished, assuming a single failure.

Evaluation Against GDC 44

During normal operation, the normal heat sink (NHS) system transfers heat from plant equipment to the environment. If the NHS system is not available, heat removal is performed by the ultimate heat sink (UHS). The UHS is a passive safety feature and includes the IC Pools, Reactor Cavity Pool, Fuel Pool, and Equipment Pool. Reactor residual heat is transferred through the ICS to the Isolation Condenser pools during off-normal conditions, including AOO event sequences, DBA event sequences, and DEC event sequences.

Heat from the containment is transferred to the equipment pool and reactor cavity pool by the PCCS, as discussed for GDC 38. Decay heat from fuel in the fuel pool can be removed by its volume of water as discussed for GDC 61. During refueling, the decay heat for the fuel in the RPV can be removed by the ultimate heat sink.

The IC Pool volumes are independent from the Equipment Pool, Fuel Pool, and Reactor Cavity Pool.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 44 are met.

Additional information discussing the compliance approach to GDC 44 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.4.16 GDC 45 – Inspection of Cooling Water System

GDC 45 Statement

The cooling water system shall be designed to permit appropriate periodic inspection of important components, such as heat exchangers and piping, to assure the integrity and capability of the system.

Evaluation Against GDC 45

The ICS heat exchangers are located above containment in the RB and can be made accessible for periodic inspections. During outages, the IC pool compartments can be drained to permit inspection of the pools and condensers.

See GDC 39 for discussion of inspection of the PCCS.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 45 are met.

Additional information discussing the compliance approach to GDC 45 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.4.17 GDC 46 – Testing of Cooling Water System

GDC 46 Statement

The cooling water system shall be designed to permit appropriate periodic pressure and functional testing to assure (1) the structural and leaktight integrity of its components, (2) the operability and the performance of the active components of the system, and (3) the operability of the system as a whole and, under conditions as close to design as practical, the performance of the full operational sequence that brings the system into operation for reactor shutdown and for loss-of-coolant accidents, including operation of applicable portions of the protection system and the transfer between normal and emergency power sources.

Evaluation Against GDC 46

The ICS is designed to allow the performance of surveillance testing in accordance with plant TSs. The ICS performance testing also confirms the proper functioning of the IC pools in support of heat removal. Each ICS train will be tested for heat transfer performance on a rotating basis.

Maintenance and testing activities are expected to be minimal as the only active mechanical components are the two per-train condensate return valves, the two per-train standby gas purge isolation valves and the two per-A and -B train Shutdown Cooling System (SDC) interface CIVs. The IC pools used as the heat sink perform their function without reliance on active component actuations.

See GDC 37 for discussion of testing of ICS. See GDC 40 for discussion of testing of the PCCS.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 46 are met.

Additional information discussing the compliance approach to GDC 46 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.5 Group V – Reactor Containment

3.1.5.1 GDC 50 – Containment Design Basis

GDC 50 Statement

The reactor containment structure, including access openings, penetrations, and the containment heat removal system shall be designed so that the containment structure and its internal compartments can accommodate, without exceeding the design leakage rate and with sufficient margin, the calculated pressure and temperature conditions resulting from any loss-of-coolant accident. This margin shall reflect consideration of (1) the effects of potential energy sources which have not been included in the determination of the peak conditions, such as energy in steam generators and as required by 50.44 energy from metal-water and other chemical reactions that may result from degradation but not total failure of emergency core cooling functioning, (2) the limited experience and experimental data available for defining accident phenomena and containment responses, and (3) the conservatism of the calculational model and input parameters.

Evaluation Against GDC 50

Containment design is based upon consideration of a full spectrum of postulated accidents that would result in the release of reactor coolant to the containment. These accidents are evaluated using Transient Reactor Analysis Code General Electric (TRACG) as boundary condition to GOTHIC to calculate containment response. These accidents include liquid, steam, and partial (both steam and liquid) breaks. The evaluation of the containment design is based upon enveloping the results of this range of analyses, plus provision for appropriate margin. The most limiting short-term and long-term pressure and temperature responses are assessed to verify the integrity of the containment structure. The GOTHIC computer methodology for measuring containment response is provided in NEDC-33922P-A, “BWRX-300 Containment Evaluation Method,” (Reference 3.1-5). BWRX-300 does not have potential energy sources that are not accounted for in calculating the mass and energy release from RPV.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 50 are met.

Additional information discussing the compliance approach to GDC 50 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.5.2 GDC 51 – Fracture Prevention of Containment Pressure Boundary

GDC 51 Statement

The reactor containment boundary shall be designed with sufficient margin to assure that under operating, maintenance, testing, and postulated accident conditions (1) its ferritic materials behave in a nonbrittle manner and (2) the probability of rapidly propagating fracture is minimized. The design shall reflect consideration of service temperatures and other conditions of the

containment boundary material during operation, maintenance, testing, and postulated accident conditions, and the uncertainties in determining (1) material properties, (2) residual, steady-state, and transient stresses, and (3) size of flaws.

Evaluation Against GDC 51

The BWRX-300 containment possesses ductility and energy absorbing capacity, which permits inelastic deformation without failure. The seismic design is qualified to meet the ductility detailing and design requirements for steel and steel composite structures of ANSI/AISC N690-18, “Specification for Safety-Related Steel Structures for Nuclear Facilities,” (Reference 3.1-10), with the supplementary guidance of RG 1.243, “Safety-Related Steel Structures and Steel-Plate Composite Walls for other than Reactor Vessels and Containments.” Additionally, the ductility is confirmed by the ultimate capacity analysis of the BWRX-300 containment. The design material selection reflects consideration of service temperatures and other conditions of the pressure boundary during operation, maintenance, testing, and DBA conditions, and the uncertainties in determining: (a) material properties; (b) residual, steady-state, and transient stresses; and (c) the size of flaws. The steel composite design is capable of containing the loads resulting from design basis transients and accidents, including dynamic loads due to seismic and high-energy piping system events.

The preoperational test program and the QA program ensure the integrity of the containment and its ability to meet all normal operating and accident requirements.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 51 are met.

Additional information discussing the compliance approach to GDC 51 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.5.3 GDC 52 – Capability for Containment Leakage Rate Testing

GDC 52 Statement

The reactor containment and other equipment which may be subjected to containment test conditions shall be designed so that periodic integrated leakage rate testing can be conducted at containment design pressure.

Evaluation Against GDC 52

The BWRX-300 containment and other equipment that may be subjected to containment test conditions are designed so that periodic integrated leakage rate testing can be conducted at containment design pressure at periodic intervals in accordance with 10 CFR 50, Appendix J.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 52 are met.

Additional information discussing the compliance approach to GDC 52 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.5.4 GDC 53 – Provisions for Containment Testing and Inspection

GDC 53 Statement

The reactor containment shall be designed to permit (1) appropriate periodic inspection of all important areas, such as penetrations, (2) an appropriate surveillance program, and (3) periodic testing at containment design pressure of the leaktightness of penetrations which have resilient seals and expansion bellows.

Evaluation Against GDC 53

The BWRX-300 containment and associated penetrations have provisions for conducting individual leakage rate tests on applicable penetrations. Penetrations are visually inspected and pressure tested for leaktightness at periodic intervals in accordance with 10 CFR 50, Appendix J.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 53 are met.

Additional information discussing the compliance approach to GDC 53 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.5.5 GDC 54 – Piping Systems Penetrating Containment

GDC 54 Statement

Piping systems penetrating primary reactor containment shall be provided with leak detection, isolation, and containment capabilities having redundancy, reliability, and performance capabilities which reflect the importance to safety of isolating these piping systems. Such piping systems shall be designed with a capability to test periodically the operability of the isolation valves and associated apparatus and to determine if valve leakage is within acceptable limits.

Evaluation Against GDC 54

Piping systems that penetrate containment are designed to provide the required isolation and testing capabilities. These piping systems are provided with test connections to allow periodic leak detection as necessary to determine if valve leakage is within acceptable limits in accordance with 10 CFR 50, Appendix J and the IST Program.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 54 are met.

Additional information discussing the compliance approach to GDC 54 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.5.6 GDC 55 – Reactor Coolant Pressure Boundary Penetrating Containment

GDC 55 Statement

Each line that is part of the reactor coolant pressure boundary and that penetrates primary reactor containment shall be provided with containment isolation valves as follows, unless it can be demonstrated that the containment isolation provisions for a specific class of lines, such as instrument lines, are acceptable on some other defined basis:

1. One locked closed isolation valve inside and one locked closed isolation valve outside containment; or

2. One automatic isolation valve inside and one locked closed isolation valve outside containment; or

3. One locked closed isolation valve inside and one automatic isolation valve outside containment. A simple check valve may not be used as the automatic isolation valve outside containment; or

4. One automatic isolation valve inside and one automatic isolation valve outside containment. A simple check valve may not be used as the automatic isolation valve outside containment.

Isolation valves outside containment shall be located as close to containment as practical and upon loss of actuating power, automatic isolation valves shall be designed to take the position that provides greater safety.

Other appropriate requirements to minimize the probability or consequences of an accidental rupture of these lines or of lines connected to them shall be provided as necessary to assure adequate safety. Determination of the appropriateness of these requirements, such as higher quality in design, fabrication, and testing, additional provisions for inservice inspection, protection against more severe natural phenomena, and additional isolation valves and containment, shall include consideration of the population density, use characteristics, and physical characteristics of the site environs.

Evaluation Against GDC 55

Each process line that penetrates the containment boundary and is part of the RCPB is provided with two in-series CIVs that are independently able to isolate the line with single failure proof automatic isolation. For systems with integral RIVs, either RIV can perform the inboard CIV function. The CIVs outside containment are located as close to the containment boundary as practicable. The integral RIV design includes design features that provide redundancy in components and features, including isolation capability, because the worst-case single failure can only affect one valve, and their design function can be accomplished with the remaining valve in each integral RIV body. Process line configurations are designed for containment leakage rate testing and inservice testing programs that include functional testing, local leakage rate testing, and Integrated Leakage Rate Testing (ILRT). Automatic isolation valves are designed to take the position that provides greater safety upon loss of actuating power.

The Nuclear Boiler System (NBS), Reactor Water Cleanup System (CUW), and Condensate and Feedwater Heating System (CFS) have inboard integral RIVs and outboard CIVs. The supply lines for Shutdown Cooling System (SDC) Trains A and B are part of the ICS and comply with GDC 55 with an outboard CIV and the inboard ICS RIVs. The injection line for the Boron Injection System (BIS) complies with GDC 55 with an outboard CIV and an inboard CIV.

Process lines that comply with GDC 55 on an “other defined basis” are:

- ICS, which can be isolated by the integral RIVs inside containment and is a closed loop design outside containment. The ICS steam supply and condensate return lines to the RPV each have an integral RIV inside containment. The ICS steam supply line to the isolation condensers is inside a guard pipe. This arrangement complies with GDC 55 based on an “other defined basis” because integral RIVs function as inboard CIVs for both steam supply and condensate return lines and the closed-loop piping outside containment can prevent radioactive releases outside containment.
- CRD uses internal ball check valves that serve as the automatic isolation CIV inside containment to isolate the hydraulic lines to the FMCRDs. A manual isolation valve is provided outside containment to isolate the HCU from the hydraulic insertion line. This configuration complies with GDC 55 based on an “other defined basis” because keeping flow path open is necessary to perform the scram function and comparing risk between a degraded scram function and the negative radioactive fission product releases without an outboard automatic CIV, the scram function demonstrates higher risk significance; thus, automatic isolation is not required.

Instrument lines are provided with excess flow check valves located outside containment meeting RG 1.11, “Instrument Lines Penetrating the Primary Reactor Containment,” and comply with GDC 55 on an “other defined basis.”

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 55 are met.

Additional information discussing the compliance approach to GDC 55 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.5.7 GDC 56 – Primary Containment Isolation

GDC 56 Statement

Each line that connects directly to the containment atmosphere and penetrates primary reactor containment shall be provided with containment isolation valves as follows, unless it can be demonstrated that the containment isolation provisions for a specific class of lines, such as instrument lines, are acceptable on some other defined basis:

1. One locked closed isolation valve inside and one locked closed isolation valve outside containment; or

2. One automatic isolation valve inside and one locked closed isolation valve outside containment; or

3. One locked closed isolation valve inside and one automatic isolation valve outside containment. A simple check valve may not be used as the automatic isolation valve outside containment; or

4. One automatic isolation valve inside and one automatic isolation valve outside containment. A simple check valve may not be used as the automatic isolation valve outside containment.

Isolation valves outside containment shall be located as close to the containment as practical and upon loss of actuating power, automatic isolation valves shall be designed to take the position that provides greater safety.

Evaluation Against GDC 56

Each process line that connects directly to the containment atmosphere and penetrates the containment boundary is provided with in-series CIVs that are independently able to isolate the line with single failure proof automatic isolation. The CIVs outside containment are located as close to the containment boundary as practicable. Automatic isolation valves are designed to take the position that provides greater safety upon loss of actuating power.

The Containment Monitoring Subsystem (CMon), Chilled Water Equipment (CWE), Plant Pneumatics System (PPS), Demineralized Water Storage and Distribution Subsystem, and Liquid Waste Management System (LWM) process lines have inboard and outboard CIVs.

The Containment Inerting System (CIS) and the Equipment and Floor Drain System (EFS) process lines comply with GDC 56 on an “other defined basis.” The CIS and EFS process lines have two CIVs outside containment because locating a valve inside containment is not practicable.

Instrument lines are provided with excess flow check valves located outside containment meeting RG 1.11 and comply with GDC 56 on an “other defined basis.”

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 56 are met.

Additional information discussing the compliance approach to GDC 56 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.5.8 GDC 57 – Closed System Isolation Valves

GDC 57 Statement

Each line that penetrates primary reactor containment and is neither part of the reactor coolant pressure boundary nor connected directly to the containment atmosphere shall have at least one containment isolation valve which shall be either automatic, or locked closed, or capable of remote manual operation. This valve shall be outside containment and located as close to the containment as practical. A simple check valve may not be used as the automatic isolation valve.

Evaluation Against GDC 57

The PCCS is a closed system inside containment that penetrates the containment boundary and is neither part of the RCPB nor connected directly to the containment atmosphere. The PCCS has three trains that each have one remote manually-operated CIV on the supply line and one remote manually-operated CIV on the return line. Both CIVs are outside containment and located as close to the containment wall as practical.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 57 are met.

Additional information discussing the compliance approach to GDC 57 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.6 Group VI – Fuel and Radioactivity Control

3.1.6.1 GDC 60 – Control of Releases of Radioactive Materials to the Environment

The nuclear power unit design shall include means to control suitably the release of radioactive materials in gaseous and liquid effluents and to handle radioactive solid wastes produced during normal reactor operation, including anticipated operational occurrences. Sufficient holdup capacity shall be provided for retention of gaseous and liquid effluents containing radioactive materials, particularly where unfavorable site environmental conditions can be expected to impose unusual operational limitations upon the release of such effluents to the environment.

Evaluation Against GDC 60

Gaseous releases come primarily from the Offgas System and the ventilation systems. Noble gases and radioiodine activity that enters the Offgas System are held-up by activated carbon charcoal adsorber beds, allowing for the decay of these gases. Ventilation releases are through the Plant Vent stack located in the Turbine Building. Automatic isolation functions are provided in the event of high radiation detection.

The LWM design has the capability to process liquid waste from normal operation as well as from occasional emergent issues, for reuse by other plant systems. In the unlikely event that the plant's overall water inventory will not allow for the water to be recycled, the filtered water can be discharged to the environment. Any environmental discharge is controlled to ensure concentrations of contaminants are maintained within permissible limits.

The Solid Waste Management System (SWM) is designed to handle solid waste generated by the plant during normal operations and AOOs. The SWM includes design features that prevent the release of liquid or gaseous effluents from the system to the environment.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 60 are met.

Additional information discussing the compliance approach to GDC 60 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.6.2 GDC 61 – Fuel Storage and Handling and Radioactivity Control

GDC 61 Statement

The fuel storage and handling, radioactive waste, and other systems which may contain radioactivity shall be designed to assure adequate safety under normal and postulated accident conditions. These systems shall be designed (1) with a capability to permit appropriate periodic inspection and testing of components important to safety, (2) with suitable shielding for radiation protection, (3) with appropriate containment, confinement, and filtering systems, (4) with a residual heat removal capability having reliability and testability that reflects the importance to safety of decay heat and other residual heat removal, and (5) to prevent significant reduction in fuel storage coolant inventory under accident conditions.

Evaluation Against GDC 61

The fuel pool has adequate water shielding for stored spent fuel. Adequate shielding for transporting fuel is also provided between the RPV and fuel pool. Sensors are installed to detect low pool water level. The fuel pool is designed with no penetrations below the water level that is needed for adequate shielding at the operating floor. Anti-siphoning provisions protect against draining the fuel pool in the event of a line break.

Fuel racks are provided in the fuel pool adjacent to the reactor cavity. The fuel racks are top loading, allowing for inspection of the cells and identification of individual fuel assemblies from the poolside or refueling platform. The fuel rack design allows natural convection from the space underneath of the rack up through the fuel seating elevation to ensure adequate cooling water flow to all stored fuel assemblies removing decay heat under normal and abnormal conditions.

The Fuel Pool Cooling and Cleanup System (FPC) normally removes decay heat from the fuel pool. Without the active cooling trains of the FPC, sufficient pool water inventory is provided to permit boiling for up to 7-days without makeup. If required, makeup water is provided from onsite sources. FPC piping is used to transport makeup water to the fuel pool from various sources in accordance with the FLEX/EME strategy; this includes a connecting point in the yard area to portable water sources.

The refueling platform includes a load handling system designed to safely handle, store, and support inspection of fuel and core components. The refueling platform handles fuel within the reactor, lifts from the reactor to the fuel pool, and is utilized to load casks for long term storage of spent fuel. The load handling system design ensures that no single probable event or component failure results in dropping or damaging a fuel assembly. The refueling platform components allow access for inspection and surveillance and maintenance activities. Mechanical stops and interlocks are provided to prevent damage to fuel assemblies and conditions that pose a radiation hazard or unintentional exposure risk to personnel. Travel limits physically block hoisting of fuel and components above approved levels ensuring exposure is kept as low as reasonably achievable.

The fuel storage and handling systems are designed to ensure adequate safety under normal and postulated abnormal conditions.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 61 are met.

Additional information discussing the compliance approach to GDC 61 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.6.3 GDC 62 – Prevention of Criticality in Fuel Storage and Handling

GDC 62 Statement

Criticality in the fuel storage and handling system shall be prevented by physical systems or processes, preferably by use of geometrically safe configurations.

Evaluation Against GDC 62

Fuel handling and storage facilities are provided to preclude inadvertent criticality during handling and storage of new and spent fuel. Criticality of fuel stored in the fuel pool is prevented by racks made of fixed neutron absorbing material maintained in geometrically safe storage and subcritical arrays during normal and credible abnormal conditions. Criticality in the fuel racks is prevented by presence of fixed neutron absorbing material. The fuel racks are Seismic Category I components.

The new and spent fuel is stored under water in the fuel pool. A full array of loaded spent fuel racks is designed to be subcritical. Neutron absorbing material, as an integral part of the rack design, is employed to assure that the calculated K_{eff}, including biases and uncertainties, does not exceed 0.95 under all normal and abnormal conditions. The abnormal conditions accounted for are an earthquake, accidental dropping of equipment, or impact caused by the horizontal movement of the fuel handling equipment without first disengaging the fuel from the hoisting equipment.

Refueling interlocks include circuitry that senses conditions of the refueling equipment and the control rods. These interlocks reinforce the operational procedures that prohibit making the reactor critical. The fuel handling system is designed to provide a safe, effective means of transporting and handling and is designed to minimize the possibility of mishandling or maloperation.

Fuel handling equipment is designed to prevent inadvertent criticality and to maintain shielding and cooling of spent fuel as necessary to meet operating and off-site dose constraints.

The presence of fixed neutron absorbing material in the fuel racks and the design of fuel handling systems precludes accidental criticality.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 62 are met.

Additional information discussing the compliance approach to GDC 62 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.6.4 GDC 63 – Monitoring Fuel and Waste Storage

GDC 63 Statement

Appropriate systems shall be provided in fuel storage and radioactive waste systems and associated handling areas (1) to detect conditions that may result in loss of residual heat removal capability and excessive radiation levels and (2) to initiate appropriate safety actions.

Evaluation Against GDC 63

Fuel pool temperature and level are monitored as part of the FPC. High pool temperature would signal the need for providing additional cooling. Area radiation monitors are provided as part of the Area Radiation Monitoring System, which monitors the operating/refueling floors for high radiation levels.

The LWM and SWM have no active decay heat removal functions because the decay heat from the activity in the inputs to these systems is not sufficient to warrant concern. Radwaste Building (RWB) area radiation monitors are provided to monitor radiation levels in the RWB.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 63 are met.

Additional information discussing the compliance approach to GDC 63 is described in the applicable PSAR sections listed in Table 3.1-1.

3.1.6.5 GDC 64 – Monitoring Radioactivity Releases

GDC 64 Statement

Means shall be provided for monitoring the reactor containment atmosphere, spaces containing components for recirculation of loss-of-coolant accident fluids, effluent discharge paths, and the plant environs for radioactivity that may be released from normal operations, including anticipated operational occurrences, and from postulated accidents.

Evaluation Against GDC 64

The BWRX-300 is provided with the following subsystems to monitor for radioactivity releases from normal operations, AOOs, and DBAs:

- A Process Radiation Monitoring Subsystem, which monitors various process and effluent streams for potentially hazardous contamination such as radioactivity, noble gases, air particulates, and halogens.
- An Area Radiation Monitoring Subsystem, which monitors gamma radiation levels in strategic locations throughout the plant.
- A Containment Monitoring Subsystem, which monitors containment pressure, containment temperature, containment water level, containment hydrogen concentration, containment oxygen concentration, containment fission products, and containment area radiation levels.

Note that the BWRX-300 design does not include a “recirculation” mode for LOCAs in which post-accident fluids are recirculated.

Accordingly, the requirements of 10 CFR 50, Appendix A, GDC 64 are met.

Additional information discussing the compliance approach to GDC 64 is described in the applicable PSAR sections listed in Table 3.1-1.

3.2 Classification of Structures, Systems, and Components

Section 4.0 of NEDC-33934P, "BWRX-300 Safety Strategy," (Reference 3.2-1), describes the approach to classifying SSCs as identifying functions that affect nuclear safety, assigning a safety category to those functions based on their importance, and then assigning a safety class to the components that perform those functions.

The primary factors influencing the outcome of SSC classification are:

- Consequences of failure to perform the functions
- Expected frequency of an SSC being called on to perform its functions
- Time following a postulated initiating event (PIE) at which, or the period for which, the SSC performs its functions

Safety importance of plant functions (i.e., defense line (DL) functions) is determined based on how functions are credited to mitigate PIEs and event sequences in the deterministic safety analysis (DSA). The organization of PIEs and event sequences is based on event categories, which reflect the frequency of occurrence of the PIE or event sequence from the probabilistic safety analysis (PSA).

The BWRX-300 Safety Strategy defines the fundamental safety functions (FSF) that protect physical barriers. For a given event sequence, if the functional DLs required to fulfill the FSFs are performed successfully, then the corresponding physical barriers remain effective.

The FSFs for the BWRX-300 are as follows:

- Control of reactivity
- Removal of heat from the fuel (in the reactor, during fuel storage and including long-term heat removal)
- Confinement of radioactive material, shielding against radiation and control of planned radioactive releases, as well as limitation of accidental radioactive releases

A systematic approach is taken to identify functions that are necessary to fulfill the FSFs and to identify the inherent features that contribute to fulfilling or affecting the FSFs. The results of applying the systematic approach are in the fault list, which provides traceability between DL functions with a direct role in fulfilling an FSF, plant states and event sequences in which each function performs that role.

Subsection 3.2.1 through Subsection 3.2.5 below summarize each area of the approach to classifying SSCs described in further detail in Sections 4.2 through 4.6 of NEDC-33934P:

- Assignment of Safety Category to Functions (Section 4.2)
- Assignment of Safety Class to Components (Section 4.3)
- Seismic Categorization (Section 4.5)
- Quality Group (Section 4.6)

3.2.1 Assignment of Safety Category to Functions

Section 4.2 of NEDC-33934P describes the process for assigning safety categories to functions. This process is illustrated in NEDC-33934P, Table 4-1: Functional Safety Category Assignment, and identifies the SSC functions that apply to each safety category for the following groups of functions:

- DL2 functions—Actively control key plant parameters associated with FSFs and detect and mitigate anticipated operational occurrence (AOO) PIEs.
- DL3 functions—Detect and mitigate design basis accident (DBA) PIEs and event sequences comprising AOO PIEs and failure of DL2 functions.
- DL4a functions—Detect and mitigate design extension conditions (DEC), including event sequences associated with some DBA PIEs and failure of DL3 functions.
- DL4b Functions—Detect and mitigate DECs to prevent core damage or mitigate the consequences of core damage events (severe accidents).
- Normal Functions—Functions typically operating during normal plant operation
- Post-Accident Monitoring (PAM) Functions—Support monitoring and display of PAMs variables

NEDC-33934P assigns each of these functions to a safety category based on importance: Safety Category 1, Safety Category 2, Safety Category 3, or Safety Category N.

3.2.2 Assignment of Safety Class to Components

Section 4.3 of NEDC-33934P provides a description of the process for assigning safety class to components. Safety class is assigned to components based on the safety category of the functions they perform as follows:

- Components that are required to perform Safety Category 1 functions are assigned to SC1.
- Components that are required to perform Safety Category 2 functions are assigned to at least SC2.
- Components that are required to perform Safety Category 3 functions are assigned to at least SC3.
- Non-Safety Class (SCN) is assigned to all other components.

In addition, the following classifications are made for components and structures that perform FSFs but may not be explicitly defined as part of a DL function:

- Components that perform a FSF, whose failure is considered “practically eliminated,” are assigned to SC1. An example is the reactor pressure vessel.
- Components that make up the fission product barriers (i.e., fuel cladding, reactor coolant pressure boundary (RCPB), and containment) are assigned to SC1.
- Components that are part of the RCPB, as defined in 10 CFR 50.2, are assigned to SC1.

- Structures (excluding fuel handling equipment) are assigned a safety classification based on the highest safety classification of the components they house or support, excluding components whose failure, due to failure of the structure, results in fail-safe performance of the component's safety category function(s).

NEDC-33934P, Table 5-1: Safety Class and Safety Category Mapping to USNRC Regulatory Requirements and Guidance, provides an overview of the assignment of safety class to components. Table 3A-1 identifies the safety classification of components.

3.2.3 Seismic Categorization

Seismic categorization of structures and components is based on the importance of functions performed, as described in NEDC-33934P, and summarized using nomenclature selected for the CRN site. SC1 components that perform Safety Category 1 functions are Seismic Category I, except that SC1 components not in a Seismic Category I structure whose failure results in fail-safe performance of the component's Safety Category 1 function are not required to be Seismic Category I. Structures and components that are significant contributors to PSA risk for seismic events are categorized as Seismic Category I. Structures and components that are not required to remain functional during or after a seismic event but whose failure during a seismic event could adversely affect the ability of any Seismic Category I structure or component to accomplish its Safety Category 1 function are classified as Seismic Category II. Structures and components for management and storage of radiological material that meet the criteria for RW-IIa in RG 1.143, "Design Guidance for Radioactive Waste Management Systems, Structures, and Components Installed in Light-Water-Cooled Nuclear Power Plants," are classified as Seismic Category "RW-IIa." Structures and components that fit none of these categories are categorized as Seismic Category "Non-Seismic." Table 3A-1 identifies the seismic categorization of components.

The seismic categorization approach described in NEDC-33934P is an alternative approach to RG 1.29, "Seismic Design Classification for Nuclear Power Plants," Position C.1. RG 1.29, Position C.1, provides a discrete list of SSCs expected to be Seismic Category I, while the BWRX-300 seismic categorization approach is based on the importance of functions being performed within the BWRX-300 design. The BWRX-300 design conforms with RG 1.29, Positions C.2, C.3 and C.4. This approach is consistent with requirements of GDC 2, 10 CFR 100, Appendix A, and 10 CFR 50, Appendix S.

In addition, the BWRX-300 seismic categorization conforms with to the following RG:

- RG 1.143, "Design Guidance for Radioactive Waste Management Systems, Structures, and Components Installed in Light-Water-Cooled Nuclear Power Plants."

The BWRX-300 seismic design is discussed in Section 3.7. The seismic categories of structures are provided in Table 3A-2.

3.2.4 Quality Group

The Quality Group designation per RG 1.26, “Quality Group Classifications and Standards for Water-, Steam-, and Radioactive-Waste-Containing Components of Nuclear Power Plants,” is used for establishing the appropriate codes and standards based on the importance of the pressure-retaining function of BWRX-300 components. Components are classified as Quality Group A, B, C, D, or not applicable. Table 3A-1 identifies the Quality Group of components.

3.3 Wind and Tornado Loadings

The BWRX-300 Seismic Category I structures are designed to withstand the effects of extreme wind (tornado and hurricane) loadings in conformance with 10 Code of Federal Regulations (CFR) 50 Appendix A, General Design Criteria (GDC) 2, following the Nuclear Regulatory Report (NUREG)-0800 Standard Review Plan (SRP) 3.3.1 and 3.3.2. Overall compliance to GDC 2, for wind and tornado is provided in Subsection 3.1.1. BWRX-300 design meets the GDC 2 requirements by following the applicable guidance provided in RG 1.143, “Design Guidance for Radioactive Waste Management Systems, Structures, and Components Installed in Light-Water-Cooled Nuclear Power Plants,” RG 1.221, “Design-Basis Hurricane and Hurricane Missiles for Nuclear Power Plants,” and RG 1.76, “Design Basis Tornado and Tornado Missiles for Nuclear Power Plants,” for the wind protection. Safety Class 1 (SC1) Structures, Systems, and Components (SSCs) are listed in Table 3A-1.

3.3.1 Wind Loadings

As discussed in NUREG-0800, SRP 3.3.1, the design wind speed, its recurrence interval, the speed variation with height, and the applicable gust factors are used in defining the input parameters for the structural design criteria appropriate to account for wind loadings. The procedures used to transform the design wind speed into an effective pressure applied to structures take into consideration the geometrical configuration and physical characteristics of the structures and the distribution of wind pressure on the structures.

3.3.1.1 Design Wind Speed and Recurrence Interval

The design wind speed is defined as the (straight-line) 3-second gust wind speed based on appropriate standards, with suitable corrections for local conditions per SRP 2.3.1. Seismic Category I structures are designed for a basic wind speed value of 71.5 m/s (160 mph) based on American Society of Civil Engineers/Structural Engineering Institute (ASCE/SEI) 7-16, “Minimum Design Loads and Associated Criteria for Buildings and Other Structures,” (Reference 3.3-1), Risk Category IV, basic wind speed maps (3-second gust), which correspond to a mean recurrence interval of 3,000 years.

The site-specific value listed in Table 2.0-1R is from the Early Site Permit Application that was calculated using ASCE/SEI 7-05 and has a recurrence interval of 100 years and remains the design-basis wind speed for the Clinch River site. The basic wind speed used in the design of Seismic Category I structures, (i.e., 71.5 m/s (160 mph)) when adjusted for the ASCE/SEI 7-05 importance factor, bounds the most severe wind that has been historically reported for the site and surrounding area with sufficient margin for the limited accuracy, quantity, and period of time in which historical data has been accumulated.

3.3.1.2 Determination of Applied Forces

Design wind speeds for the Seismic Category I structures are translated into structural loading in accordance with the methodology specified in ASCE/SEI 7-16 (Reference 3.3-1). Appropriate load combinations (including wind) to be used in design are given in American National Standards Institute/American Institute of Steel Construction (ANSI/AISC) N690-18, “Specification

for Safety-Related Steel Structures for Nuclear Facilities," (Reference 3.3-2). Procedures used are in conformance with Subsection II of SRP 3.3.1. However, NUREG-0800, SRP 3.3.1 refers to the ASCE/SEI 7-05 version. The BWRX-300 design uses the ASCE/SEI 7-16 version. A comparison performed between these two ASCE/SEI versions concludes that the ASCE/SEI 7-16 version bounds the ASCE/SEI 7-05 design parameters.

3.3.2 Extreme Wind (Tornado & Hurricane) Loadings

3.3.2.1 Applicable Design Parameters

The design input tornado and hurricane wind parameters applicable to the Seismic Category I structures are listed in Table 2.0-1R. The tornado wind design parameters bound the hurricane wind design parameters and the wind that has been historically reported for the site and surrounding area with sufficient margin for the limited accuracy, quantity, and period of time in which historical data has been accumulated. Civil structures supporting and protecting SSCs for storage and processing of radioactive gas, liquid, and solid materials are classified in accordance with Regulatory Position 5 of RG 1.143. RW-IIa class SSCs are designed to withstand the tornado wind demand of Table 2 of RG 1.143. The Control Building (CB), including the Main Control Room (MCR) and egress route from the MCR to the Secondary Control Room (SCR) in the Reactor Building (RB), is designed to maintain its structural integrity under an extreme wind event to prevent incapacitating injury to MCR occupants or their egress to SCR in the RB, as discussed further in Subsection 3.8.4.4.

3.3.2.2 Determination of Forces on Structures

The procedures for transforming tornado wind speed into pressure-induced forces to apply to structures and the distribution across the structures are based on BC-TOP-3-A, "Tornado and Extreme Wind Design Criteria for Nuclear Power Plants," (Reference 3.3-3) and follow the guidance of RG 1.76.

The procedure for transforming the tornado-generated missile impact into an effective or equivalent static load on structures is given in Subsection 3.5.3. The tornado missile spectrum is discussed in Subsection 3.5.1.4.

The individual tornado loading components and the load factors are in accordance with SRP 3.3.2/ BC-TOP-3-A and are selected to produce the most adverse total tornado effect on structures. The combined tornado effects are determined based on Equations 1 and 2 provided in SRP 3.3.2. The factor of 1.2 specified in BC-TOP-3-A, Sections 3.4 and 3.5.2 is applied to recognize potential non-conservative results for external walls when using the formulas specified in Appendix D of BC-TOP-3-A due to potential three-dimensional effects. As the formulas in Appendix D of BC-TOP-3-A are not used the 1.2 factor is not applied for the BWRX-300 design.

SRP 3.3.2 invokes ASCE/SEI 7-05 for calculating maximum velocity pressure, q_z. After the values for coefficients, factors, and importance factor are substituted into the equation from SRP 3.3.2, the equation for maximum velocity pressure becomes $q_z = 0.00256V^2$, where V is the maximum tornado wind speed. This aligns with Equation 3-8 of BC-TOP-3-A. The size

coefficient, C_s, from BC-TOP-3-A considers the load distribution length and the radius of maximum tornado wind. This size coefficient is not explicitly specified in ASCE/SEI 7-05. However, the values of external pressure coefficient, C_p, in Section 4.3.2 of BC-TOP-3-A, are similar to those provided for wall pressure coefficients in Figure 6-6 of ASCE/SEI 7-05. The approach in BC-TOP-3-A and ASCE 7-05 are similar. Therefore, BC-TOP-3-A is considered to be appropriate for use in the BWRX-300 design.

As discussed in Subsection 3.3.1.2, the BWRX-300 design uses the ASCE/SEI 7-16 version, which bounds the ASCE/SEI 7-05 design parameters.

Tornado loading considers tornado wind pressures, differential pressure loads due to rapid atmospheric pressure change, and tornado or hurricane-generated missile impact. For the purpose of structural analysis, the BWRX-300 RB is an enclosed (unvented) structure. The exposed exterior roof and walls of the RB are designed for the full pressure drop as provided in Table 2.0-1R.

3.3.2.3 Effects of Failure of Structures or Components Not Designed for Tornado Loads

The Seismic Category II power block structures surrounding the RB are designed to maintain their structural integrity during an extreme wind event such that they do not collapse on the Seismic Category I RB.

Wind interaction evaluation follows the interaction requirements and guidance per the methodology described in NEDO-33914-A, “BWRX-300 Advanced Civil Construction and Design Approach,” Section 6.0 (Reference 3.3-4).

3.5 Missile Protection

The missile protection design basis for Structures, Systems, and Components (SSCs) is described in this section. General arrangement drawings showing locations of the SSCs are presented in Subsection 1.2.3.

Missiles considered are those that could result from a plant-related failure or incident including failures within and outside of containment, environmental-generated missiles, and site proximity missiles. The structures, shields, and barriers that are designed to withstand missile effects, the possible missile loadings, and the procedures to which each barrier is designed to resist missile impacts are discussed in this section. Overall compliance to GDC 2, 3 and 4 for the missile protection is provided in Subsection 3.1.1. The BWRX-300 design meets GDC 2, 3, and 4 requirements by following applicable guidance provided in RG 1.13, “Spent Fuel Storage Facility Design Basis,” RG 1.76, “Design Basis Tornado for Nuclear Power Plants,” RG 1.115, “Protection Against Low-Trajectory Turbine Missiles,” modified for a 3600 rpm turbine, RG 1.117, “Tornado Design Classification,” RG 1.143, “Design Guidance for Radioactive Waste Management Systems, Structures, and Components Installed in Light-Water-Cooled Nuclear Power Plants,” and RG 1.221, “Design-Basis Hurricane and Hurricane Missiles for Nuclear Power Plants,” for the missile protection.

Structures classified as Seismic Category I (e.g., Reactor Building (RB)), and structures classified as Seismic Category RW-IIa (e.g., Radwaste Building (RWB)) are designed to resist missiles, including missiles generated by natural phenomena. Seismic Category II and Non-Seismic structures are not required to be designed to resist missiles generated from tornado and extreme wind phenomena unless they have special tornado/hurricane storm hardening provisions. Safety Class 1 SSCs listed in Table 3A-1 are designed to be protected from the missiles.

3.5.1 Missile Selection and Description

The missile protection criteria to which the plant is designed follows GDC 2 and 4 for external missiles and GDC 4 for internal missiles. SSCs are required to be protected from a wide spectrum of missiles. Missiles are classified as internal or external.

Internally generated missiles are those resulting from in-plant equipment component failures or other events within the nuclear island as defined in SRP 3.5.1.1, “Internally Generated Missiles (Outside Containment),” and SRP 3.5.1.2, “Internally-Generated Missiles (Inside Containment).” Potential missile sources from rotating equipment, high-pressure system ruptures, and missiles caused by, or as a consequence of, gravitational effects (e.g., heavy load drop) are considered, when applicable.

Externally generated missiles are those that originate from an event of natural or human-induced origin that originates outside the site and whose effects on the reactor facility are considered as potentially hazardous. Examples include environmental-generated missiles and transportation accidents.

Potential missiles inside and outside containment and turbine missiles are identified, and their statistical significance is determined when applicable. A statistically significant missile is defined as a missile that could cause unacceptable plant consequences or exceedance of radiological release limits.

The examination of potential missiles and their consequences is done in the following manner to determine statistically significant missiles:

- If the probability of occurrence of the missile, P1, is determined to be less than 10^{-7} per year, the missile is dismissed from further consideration because at that likelihood it is considered not to be a statistically significant risk.
- If P1 is found to be greater than 10^{-7} per year, it is examined for its probability of impacting a design target P2.
- If the product of P1 and P2 is less than 10^{-7} per year, the missile is dismissed from further consideration.
- If the product of P1 and P2 is greater than 10^{-7} per year, the missile is examined for its damage probability P3. If the combined probability (i.e., P1 x P2 x P3 = P4) is less than 10^{-7} per year, the missile is dismissed.
- Finally, measures are taken to design acceptable protection against missiles with P4 greater than 10^{-7} per year to reduce P1, P2, and/or P3, so that P4 is less than 10^{-7} per year.

Preventative and mitigative measures considered in the BWRX-300 design against missiles include the following:

- Location of the system or component in an individual missile-proof structure
- Physical separation of redundant systems or components of the system from the missile trajectory path or calculated range
- Provision of localized protection shields or barriers for systems or components
- Design of the particular structure or component to withstand the impact of the most damaging missile
- Provision of design features on the potential missile source to prevent missile generation
- Orientation of the potential missile source to prevent unacceptable consequences caused by missile generation

The following criteria are considered as an acceptable design basis to withstand the statistically significant missiles:

- No loss of containment function as a result of missiles generated internal to containment
- Reasonable assurance that a safe plant shutdown condition can be achieved and maintained
- The failure of non SC1 equipment, components, or structures, whose failure could result in a missile, do not cause failure of SC1 equipment
- No high energy lines are located near the off-gas charcoal bed adsorbers (located in the RWB)

In some cases, structural walls and slabs are credited for missile-consequence mitigation from missiles generated by rotating and pressurized components. These walls and slabs are designed to withstand internal missile effects in order to preclude perforation by internally generated missiles.

3.5.1.1 Internally Generated Missiles (Outside Containment)

SSCs (outside containment) are protected from internally generated missiles in accordance with the requirements of GDC 4.

Potential missile sources from rotating equipment or high-pressure system ruptures, and missiles caused by, or as a consequence of, gravitational effects (e.g., heavy load drop) are considered in the design, where applicable.

Equipment within the general categories of pumps, fans, blowers, diesel generators, compressors, and components in systems normally functioning during power reactor operation, are examined for possible sources of credible and significant missiles.

Potential missiles that result from the failure of pressurized components are categorized as contained fluid energy missiles or stored energy (elastic) missiles.

Examples of potential contained fluid energy missiles are valve bonnets, valve stems, and retaining bolts. Valve bonnets are considered jet-propelled missiles. Valve stems are analyzed as piston-type missiles, while retaining bolts are examples of stored strain energy missiles.

BWRX-300 does not consider pressurized bottles in the design.

3.5.1.2 Internally Generated Missiles (Inside Containment)

SSCs (inside containment) are protected from internally generated missiles to ensure support to the reactor facility and conformance with the requirements of GDC 4. As discussed in Subsection 3.5.1.1, potential missile sources from both rotating equipment and pressurized components are considered, when applicable. Gravitational missiles inside the containment are also considered.

3.5.1.3 Turbine Missiles

In accordance with RG 1.115, the risk from turbine missiles is acceptably small, either because design features are provided to prevent damage or because the probability of a strike by a turbine missile is sufficiently low. The RG 1.115 hazard rate due to low trajectory turbine missiles is less than 10^{-7} per year for the loss of a safety system for a single event. However, the associated strike zone, as well as the P1 thru P3 probabilities for high-trajectory missiles, are for an 1800 rpm turbine, and will be modified to accommodate a 3600 rpm turbine speed.

Favorable turbine generator placement and orientation, combined with quality assurance in design and fabrication, maintenance, and inspection programs, and overspeed protection systems, as described in Chapter 10, provide an acceptably small risk from turbine missiles. If the risk is acceptably low, barriers are not required to protect Safety Class 1 items. General

arrangement drawings illustrating major structures are provided in Figures 1.2-3 through 1.2-15. Turbine missile characteristics, trajectory paths, and probabilities are specific to each turbine vendor and turbine type; therefore, detailed turbine missile data is provided after selection of a turbine vendor. Section 15.6.2.3.5 presents the methodology for performing a preliminary qualitative assessment for determining the probability of turbine generated missiles and their effect on target SSCs.

3.5.1.4 Missiles Generated by Extreme Winds

The possible environmental hazards are due to missiles generated by the design basis tornado and hurricane.

The design for missiles generated by tornadoes and other extreme winds meets the requirements of GDC 2 and 4. The methodology used for designing BWRX-300 complies with RG 1.76 for tornado missiles, RG 1.221 for hurricane missiles, and RG 1.143 missile spectrum for the RWB with modifications to reconcile with more recent guidance in American National Standards Institute/American Nuclear Society (ANSI/ANS)-2.3, “Estimating Tornado, Hurricane, and Extreme Straight Line Wind Characteristics at Nuclear Facility Sites,” (Reference 3.5-1) consistent with RG 1.76.

Design for missile impact includes the bounding extreme winds (tornado or hurricane) and the corresponding wind-generated missiles as listed in Table 3.5-1. The design basis tornado and hurricane missile spectrum shown in Table 3.5-1 is the most limiting natural phenomena hazard in the design of missile barriers and structures. This spectrum is considered to envelope missiles generated by less intense natural phenomena.

RG 1.76 guidelines are followed for design basis missiles for nuclear power plants which includes at least:

1. A massive high-kinetic-energy missile that deforms on impact

2. A rigid missile that tests penetration resistance

3. A small rigid missile of a size sufficient to pass through any opening in protective barriers

Non-storm-resistant building superstructures are constructed from materials such as reinforced concrete block, or structural steel with metal siding and roof deck. Potential missiles or debris from these materials, resulting from failure of the superstructure or from items blown off, when subjected to winds of tornado or hurricane intensity, are considered to be less severe than the missiles shown in Table 3.5-1.

The site-specific value for the hurricane wind speed is provided in Table 2.0-1R as 130 mph. However, the design hurricane wind speed used for determination of hurricane missile velocities for the BWRX-300 is 200 mph, which bounds the site-specific value.

3.5.1.5 Site Proximity Missiles (Except Aircraft)

As discussed in Section 2.2.3.2, the evaluations performed on potential accidents that could generate missiles (i.e., explosions) do not pose a threat to the CRN Site. Site proximity missiles are therefore dismissed from further consideration.

3.5.1.6 Aircraft Hazards

In accordance with the acceptance criteria in SRP 3.5.1.6, “Aircraft Hazards,” when the probability of aircraft accidents resulting in radiological consequences greater than the 10 CFR 100, “Reactor Site Criteria,” exposure guidelines is greater than an order of magnitude of 1E-07 per year, a detailed review of aircraft hazards is to be performed. This review determined that the total aircraft impact frequency is 5.13E-05 per year, which is greater than 1E-07 per year.

Therefore, an evaluation against a second criterion (Core Damage Frequency (CDF) less than 1E-08 per year) is performed for large aircraft and small aircraft impact. The initiating event frequency for large aircraft impact is 4.92E-07 per year. Risk CDF due to aircraft accident hazards is estimated using the following equation:

CDF = IE frequency * CCDP

Where:

IE frequency is the Initiating Event frequency,

CCDP is the Conditional Core Damage Probability

The CDF for the large aircraft impact is 6.4E-11 per year which is below 1.0E-08 per year.

For the small aircraft impact evaluation, individual CCDPs are developed for the Turbine Building (TB), Control Building (CB), RWB, Service Building, and RB. For all buildings except the RB, the CCDP is calculated assuming all SSCs associated with that building are assumed to fail. The RB is capable of withstanding a large aircraft crash and its associated engine without perforation. Therefore, Safety Class 1 (SC1) components inside the RB would remain intact and maintain their intended functions following the impact of a large commercial aircraft, which is bounding for the small aircraft impact scenario. The highest CDF for the small aircraft impact is for the CB with a CDF of 1.27E-09 per year, which is below the screening criterion of 1.0E-08 per year. Therefore, no further analysis for small aircraft impact is required for the BWRX-300 design.

A summary description of the large aircraft impact assessment required per 10 CFR 50.150 is provided in Appendix 3N.

3.5.2 Structures, Systems, and Components to be Protected from Externally Generated Missiles

This subsection discusses the SSCs to be protected from externally generated missiles that are required to safely shut down the reactor and maintain it in a safe condition. SSCs that are required to be protected from externally generated missiles are located in a structure that is

designed as storm (tornado and hurricane) resistant or other provisions are made to protect them. Seismic Category I and RW-IIa structures, and portions of the CB structure, defined by the different systems requirements, are designed to withstand the effects of externally generated missiles.

The design for missiles generated by extreme winds conforms with the Regulatory Positions C1 and C2 of RG 1.76, Regulatory Positions C1 and C2 of RG 1.221, Regulatory Positions C1, C2 and C3 of RG 1.117, and the Regulatory Position C2 of RG 1.13. SSCs to be protected from externally generated missiles are designed to meet the SRP 3.5.2, “Structures, Systems, and Components to be Protected from Externally-Generated Missiles,” acceptance criteria.

For the RWB, design for missiles is in accordance with RG 1.143.

Main Control Room (MCR) and MCR to secondary control room egress route are hardened to meet requirements of RG 1.117 to provide a qualified route for egress.

3.5.3 Barrier Design Procedures

The procedures by which structures and barriers are designed to resist the missiles described in Subsection 3.5.1 are presented in this section. The following procedures are in accordance with SRP 3.5.3, “Barrier Design Procedures” and ensure that the design of structures, shields, and barriers that need to withstand the effects of environmental and natural phenomena meet the relevant requirements of GDC 2 and GDC 4.

3.5.3.1 Local Damage Prediction

The prediction of local damage in the impact area depends on missile characteristics, the basic material of construction of the structure or barrier (i.e., reinforced concrete, steel, or steel-plate composite) or Diaphragm Plate Steel-Plate Composite (DP-SC)), and the structural response. It is assumed that the missile strikes the target normal to the surface, and the axis of the missile is assumed parallel to the line of flight. These assumptions result in a conservative estimation of local damage.

Explicit dynamic inelastic analysis may be used, in lieu of the simplified formulas, to predict the local damage modes associated with the penetration of a missile into the barrier and the minimum required thickness.

3.5.3.1.1 Concrete Structures and Barriers

Local damage modes resulting from hard missile impact to concrete structures are presented in Figure 3.5-1 adopted from R.P. Kennedy, “A Review of Procedures for the Analysis and Design of Concrete Structures to Resist Missile Impact Effect,” (Reference 3.5-2) as explained below:

- Missiles with extremely low velocity can strike the target and bounce off without creating any local damage.
- As the missile velocity increases, the concrete surface is spalled. The spall area extends larger than the missile cross-sectional area as shown in Figure 3.5-1 (a).

- As the velocity increases, the missile can penetrate the target as shown in Figure 3.5-1 (a).
- Further increase in the missile velocity can result in cracking the back surface which may result in scabbing (scabbing area is much wider than that of spalling but less deep) as shown in Figure 3.5-1 (b).
- Further increase in the missile velocity can result in perforation of the target as shown in Figure 3.5-1 (c).
- Finally, with increased velocity the missile can exit from the rear side of the target.

To prevent perforation, criteria in Appendix F, Section F.7 of ACI 349-13, “Code Requirements for Nuclear Safety-Related Concrete Structures and Commentary,” (Reference 3.5-3) is satisfied as listed below:

1. When perforation of concrete structural elements needs to be precluded, the concrete thickness is to be at least 20% greater than that required to prevent perforation.

2. Concrete structural elements protecting required systems or equipment which could be damaged by secondary missiles (fragments of scabbed concrete) are designed to prevent scabbing, or a properly designed scab shield is based on applicable formulas or pertinent test data. In the absence of scab shields, the concrete thickness is to be at least 20% greater than that required to prevent scabbing.

3. When it can be demonstrated by applicable formulas or pertinent test data that the concrete thickness is at least 20% greater than that required to prevent perforation and hence punching shear failure, design for punching shear in accordance with Section F.5 of ACI 349-13 is not required.

4. For concrete slabs or walls subjected to missile impact effects where the concrete thickness is less than twice that required to prevent perforation, the minimum percentage of reinforcement is to be 0.2% each way, each face.

Empirical equations provided in “A Review of Procedures for the Analysis and Design of Concrete Structures to Resist Missile Impact Effects,” are used to determine the required barrier thicknesses. Resulting thickness cannot be less than those listed in Table 3.5-2, which specifies the minimum thicknesses necessary to protect against tornado missiles.

3.5.3.1.2 Steel Structures and Barriers

Perforation is the local damage mode considered for a hard missile impacting steel plate. The minimum plate thickness to prevent perforation is obtained by multiplying 1.25 by the more conservative thickness of the formula described in C. R. Russel, “Reactor Safeguards,” (Reference 3.5-4) and the Stanford equation in ORNL-NSIC-5, “U.S. Reactor Containment Technology,” (Reference 3.5-5) as recommended by Bechtel Topical Report BC-TOP-9A, “Design of Structures for Missile Impact,” (Reference 3.5-6)

3.5.3.1.3 Steel-Plate Composite Barriers

Composite section barriers are utilized in the BWRX-300 for missile protection when the residual velocity of the missile perforating the first element is considered as the striking velocity for the next element for prediction of local damage in accordance with the regulatory guidance of SRP 3.5.3.

Local damage modes resulting from hard missile impact to steel-plate composite structures are presented in Figure 3.5-2, discussed in Kim, J., “Behavior, Analysis and Design of Steel-Plate Composite Walls for Impactive Loading,” (Reference 3.5-7) as follows:

- Stage 1: The missile can impact the front steel faceplate causing damage to the front faceplate or perforate through it.
- Stage 2: The missile creates a hole in the front faceplate (tunneling zone) and crushes the concrete in the contact area. Radial cracks form a frustum in the concrete which begin to push the rear steel faceplate.
- Stage 3: The concrete frustum pushes against the rear faceplate causing it to deform (bulge) in the out-of-plane direction.
- Stage 4: The missile proceeds in the concrete frustum and crushes the central area. Additional smaller frustums are created within the original one and the rear faceplate bulging increases.
- Stage 5: The missile contacts the rear faceplate and if it has enough residual velocity the missile can perforate through the rear faceplate.

Steel-plate composite structures are designed to prevent local perforation of the rear faceplate. Scabbing is not a design limit state because it is prevented by the rear steel faceplates of the steel-plate composite structure. The steel faceplate on the impact (front) side has little influence on the behavior with the exception that it constrains concrete spalling on its side. Therefore, the front faceplate is conservatively ignored per Bruhl, J. C., et. al., “Design of Composite steel-plate composite Walls to Prevent Perforation from Missile Impact,” (Reference 3.5-8). The missile penetrates the concrete infill thickness and dislodges (fractures) a conical plug of concrete (frustum) that starts moving at the same residual velocity as the impacting missile. This conical concrete plug becomes the impacting projectile on the rear steel plate, and the rear steel plate needs to stop the mass of the concrete plug and original missile to prevent perforation (plate tearing/fracture) of the steel-plate composite barrier.

When the missile impact velocity is greater than the calculated perforation velocity of the concrete infill, perforation of steel-plate composite structures by missiles is prevented by specifying steel faceplate thickness that is greater than the minimum steel plate thickness. Perforation of steel-plate composite structures is not allowed; therefore, the faceplate thickness required to prevent perforation under impactive load is to be at least 25% greater than the calculated thickness.

Steel-plate composite panel thickness required for resisting missile impact is determined by calculating the missile penetration depth in the steel-plate composite panel concrete core. A modification factor is proposed by Reference 3.5-7 to enhance the accuracy of predicting the missile penetration depth into the concrete core of steel-plate composite panels.

The missile velocity required to perforate a given wall thickness is based on the equations in Nuclear Energy Institute (NEI) 07-13, "Methodology for Performing Aircraft Impact Assessments for New Plant Designs," (Reference 3.5-9), modified as proposed by Reference 3.5-7 and Reference 3.5-8.

The minimum steel faceplate thickness required to prevent perforation of the rear steel plate by the missile and concrete plug moving together with the residual velocity is calculated per Reference 3.5-8.

3.5.3.2 Overall Damage Prediction

The overall response of a structure or barrier to missile impact depends upon the location of impact (e.g., near mid-span or near a support), dynamic properties of the structure/barrier and missile, and on the kinetic energy of the missile.

The overall response of a structure subjected to impactive load is determined by one of the following methods:

1. Energy Balance Methods: Overall response can be assessed by using energy balance techniques to demonstrate that the calculated value of the required ductility ratio, μ_r, is less than or equal to the applicable value of the permissible ductility ratio, μ_p:

    a. Williamson and Alvy, "Impact Effect of Fragments Striking Structural Elements," (Reference 3.5-10): An acceptable procedure for such an analysis, where the impact is assumed to be plastic, is presented in Reference 3.5-10. In this reference, the deformability of the missile is not considered.

    b. BC-TOP-9A: When a missile strikes a target, large forces develop at the missile target interface. If the interface forcing function is known (e.g., frontal impact of an automobile), the target structure can be modeled to predict the structural response. In this method, the deformability of the missile is accounted for in the forcing function. The overall structural response of a target is determined by equating the available target strain energy to the required strain energy to stop a missile using the analysis procedure provided in BC-TOP-9A.

2. Nonlinear Time-History Dynamic Analysis Method: The dynamic effects of impactive loads can be considered by performing a time-history dynamic analysis. The mass and inertial properties are included, as well as the nonlinear stiffnesses of the structural members under consideration.

3.5.3.3 Dynamic Increase Factors

Dynamic increase factors are based on the material strain rate effects. Increase factors are applied to static material strengths of steel, concrete, and steel-plate composite constituents for purposes of determining section strength but not to exceed those specified in Table 3.5-3.

The dynamic increase factors are limited to 1.0 for all materials where the dynamic load factor associated with the impactive loading is less than 1.2, Clause F.2.1 of ACI 349 (Reference 3.5-3) and Clause Appendix N9.1.6a of American National Standards Institute/American Institute of Steel Construction (ANSI/AISC) N690-18, “Specification for Safety-Related Steel Structures for Nuclear Facilities,” (Reference 3.5-11).

3.5.3.4 Required Ductility Ratio

Required ductility is calculated by dividing the maximum target displacement resulting from the missile impact by the component yield displacement. Maximum target displacement is estimated from the applied impact load combined with other applicable loads using one of the energy balance methods described in Williamson and Alvy (Reference 3.5-10) and Energy Balance Method, BC-TOP-9A. The component adequacy for the resulting inelastic deformation is determined by comparing the calculated required ductility ratio (μ_r) with the applicable permissible ductility ratio (μ_p) provided in Table 3.5-4 for steel and reinforced concrete and Table 3.5-5 for steel plate composite.

Applicable RG	RG 1.76[2]	RG 1.221	RG 1.143 and ANSI-2.3 [6]

Notes:

(1) Design for missile impact uses the bounding missile speeds (tornado or hurricane).

(2) Values are for Region I from RG 1.76.

(3) Only for portions requiring storm hardening (at a minimum the MCR and MCR to SCR egress route)

(4) Design basis wind speeds are nominal 3-second gust in (m/s) mph at 33 ft (10m) above ground over open terrain.

(5) The design hurricane wind speed used for determination of hurricane missile velocities for the BWRX-300 is 89.4 m/s (200 mph), which bounds the site-specific value of 58.12 m/s (130 mph).

(6) In accordance with Table 2 of RG 1.143, Design Basis tornado wind speed is based on Table 3 of ANSI/ANS-2.3 at a probability of 10^{-5}/yr consistent with RG 1.76. Horizontal and vertical velocity coefficients are based on Table 4 of ANSI/ANS-2.3. In accordance with Table 3 of ANSI/ANS-2.3 hurricanes do not occur at a probability of $1e^{-5}$/yr or less for all regions.

(7) C_DA/m missile flight parameter including drag coefficient (C_D) x projected frontal area of missile (A)/mass of missile (m).

(8) Schedule 40 pipe missile per Table 4 of ANSI/ANS-2.3 and consistent with Table 2 of RG 1.76.

(9) In accordance with Table 2 of RG 1.143, the design-basis missiles for the Radwaste building do not include the small rigid missile.

	Flexure(1)(2)-Steel plates	≤ 20	
	Flexure(1)(2)-Open sections (W, S, WT)	≤ 10	
	Flexure(1)(2)-Closed sections (pipe, box section)	≤ 20	
	Members where shear(1)(2) governs the design	≤ 5	
	Compression, applicable when $F_e \geq 4.5\ F_y$	$\leq \min\left(\frac{0.225}{F_y/F_e}, \frac{\varepsilon_{st}}{\varepsilon_y}, 10\right)$	
Reinforced Concrete Structures	Flexure(3)-Steel beams, walls, and slabs	$\min\left(\frac{0.05}{\rho-\rho'}, 10\right)$ Rotational capacity r_θ in radians of any yield hinge is limited to (0.0065 *d/c*) but not to exceed 0.07 radians	ACI 349 Clause F.3.3 and F3.4 (Reference 3.5-3)
	Shear-controlled beams, walls, and slabs: shear is resisted by concrete alone	≤ 1.0	ACI 349 Clause F.3.7 (Reference 3.5-3) as modified by RG 1.142
	Shear-controlled beams, walls, and slabs: shear is resisted by concrete and stirrups, headed bars, or bent bars	≤ 1.3	
	Shear-controlled beams, walls, and slabs: shear is resisted by stirrups alone	≤ 3.0	

Table 3.5-4 Permissible Ductility Ratios-Steel and Reinforced Concrete
(Sheet 2 of 3)

Barrier Material	Limit State	Permissible Ductility Ratio (μ_p)	Reference
Reinforced Concrete Structures (continued)	Compression and Flexural produced from impactive loads Case 1: When compression controls the design, as defined by a load-moment interaction diagram	≤ 1.0	ACI 349 Clause F.3.8 (Reference 3.5-3)
	Compression and Flexural produced from impactive loads Case 2: for beams columns, walls, and slabs When the compression load does not exceed $0.1f_c'A_g$ or one-third of that which would produce balanced strain conditions, whichever is smaller	$\min\left(\frac{0.05}{\rho-\rho'}\ 10\right)$ Rotational capacity r_θ in radians of any yield hinge is limited to (0.0065 *d/c*) but not to exceed 0.07 radians	
	The permissible ductility ratio varies linearly for conditions between those specified in Case 1 and Case 2.		
	Axial compressive load	≤ 1.3	ACI 349 Clause F.3.9 (Reference 3.5-3)

Table 3.5-4 Permissible Ductility Ratios-Steel and Reinforced Concrete
(Sheet 3 of 3)

Notes:

(1) For net sections with ductile behavior, the plastic resistance is based on yielding of the net section. For net sections with either brittle or limited ductile behavior, the member's plastic resistance is based on yielding of the gross section provided that the net section's tensile rupture based available strength exceeds its gross section's yielding based available strength.

(2) Accompanying compression force, if any, is less than the smaller of $0.1F_eA_g$ and $0.1F_yA_g$.

(3) For flexure to control the design, the shear strength of a structural member is at least 20% greater than the flexural strength; otherwise, the ductility ratios given for shear-controlled limit state are to be used.

Where:

ε_u: strain corresponding to elongation at failure (rupture) using the value corresponding to an 8-in. (200 mm) long specimen.

ε_y: strain corresponding to nominal yield stress = F_y/E

F_y: specified minimum yield stress, (ksi)

E: Modulus of elasticity 29,000 ksi (200,000 MPa) for carbon steel

ε_{st}: strain corresponding to the onset of strain hardening

F_e: elastic buckling stress determined according to $F_e = \frac{\pi^2 E}{(L_c/r)^2}$, (ksi)

r: radius of gyration, (in)

L_c: Effective length of member for buckling about the minor axis, (in)

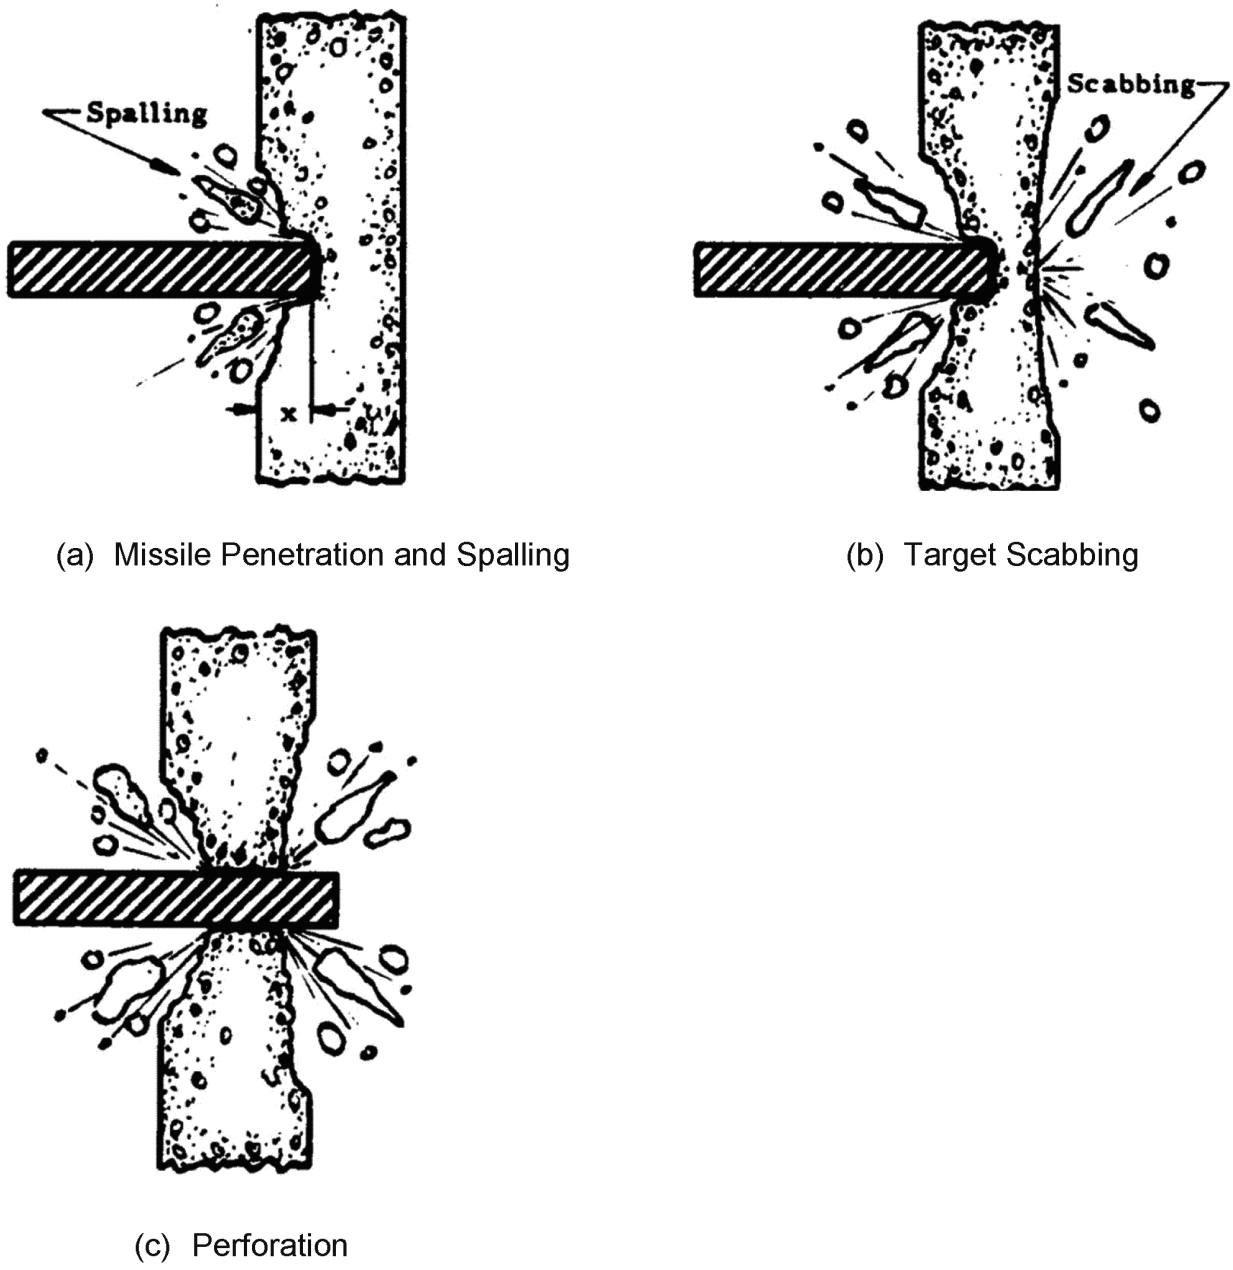
f'_c: Concrete compressive strength (psi)

A_g: Gross cross-sectional Area (in^2)

Table 3.5-5 Permissible Ductility Ratios – Steel-Plate Composite

Element Type	Controlling Behavior (1) (2)	Superficial Damage	Limited, Moderate, Severe Damage	Limited Damage	Moderate Damage	Severe Damage
			Ductility μ_d	Support Rotation r_θ (deg)(4)	Support Rotation r_θ (deg)	Support Rotation r_θ (deg)
SC Slabs and Walls (including DP-SC)	Out-of-Plane Flexure	Essentially Elastic Behavior (3)	10(4)	1	4	6
	Out-of-Plane Shear:					
	• Ties or Diaphragms spaced at no more than 1/2 t_{sc}		1.3			
	• Ties or Diaphragms spaced at more than 1/2 t_{sc}		1.0			
	Compression		1.0(5)			
SC Shear Walls, and Diaphragms (including DP-SC)	In-Plane Flexure (shear walls and diaphragms)	Essentially Elastic Behavior (3)	N/A	-	1.5	2
	In-Plane Shear (shear walls)		3.0			
	In-Plane Shear (diaphragms)		1.5			

Notes:



(1) SC components (including DP-SC) are classified as flexure-controlled if their available strength for the limit state of flexural yielding is less than their available strength for the limit state of out-of-plane shear failure by at least 25%.

(2) When impact/impulse loading results are in net tension, shear capacity of concrete is not considered.

(3) Essentially elastic behavior means elastic structural analysis using design strain acceptance criteria of 1% for steel plates and 0.35% for concrete in compression, which corresponds to superficial damage of elements. The permissible ductility ratio μ_d is 1.0.

(4) The limit of ductility of 3 can be used in lieu of support rotations of 1 degree complying with Regulatory Position C11.1.6 of RG 1.243.

(5) For additional information refer to Regulatory Position C11.1.5 of RG 1.243.

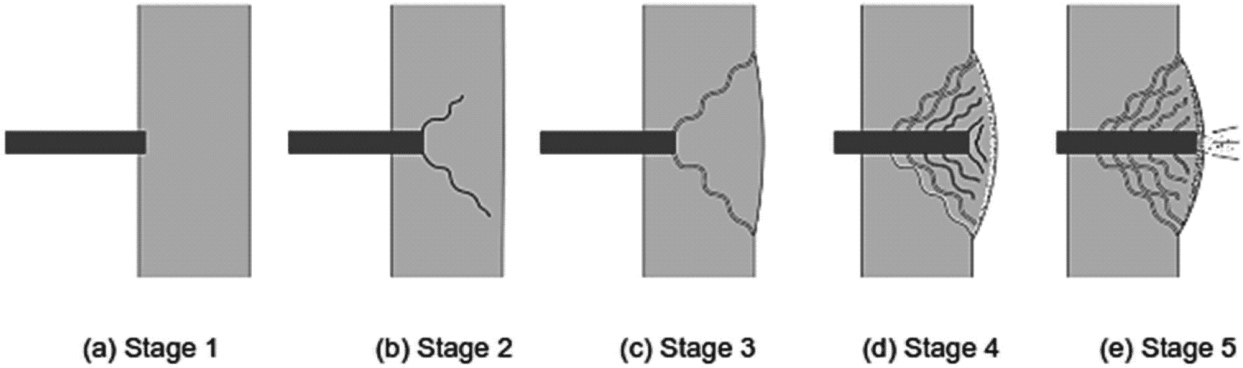

Figure 3.5-2 BWRX-300 Missile Impact Local Damage Modes for the Steel-Plate Composite Barrier

3.6 Protection Against Dynamic Effects Associated with the Postulated Rupture of Piping

In accordance with NUREG-0800 SRP 3.6.1 and 3.6.2, the plant is designed for protection against piping failures inside and outside containment so that such failures do not cause the loss of needed functions of the systems and to ensure that the plant can be safely shut down in the event of such failures. The design includes consideration of high energy and moderate energy fluid system piping located inside and outside of containment. Design bases and measures used to protect these Structures, Systems, and Components (SSCs), referred to in the following subsections as essential SSCs, are discussed in Subsection 3.6.1 and Subsection 3.6.2. Essential SSCs are those that are required to shut down the reactor and mitigate the consequences of the postulated piping failure. In addition, systems, or portions of systems, that are designed to mitigate the consequences of a postulated pipe failure are provided with design features that can assure the performance of their safety function. A list of BWRX-300 SSCs, their location, seismic category, and Quality Group is provided in Table 3A-1. Overall compliance for BWRX-300 design to GDC 4 is provided in Subsection 3.1.1.4. An analysis of pipe break events is performed in the Final Safety Analysis Report (FSAR) to identify essential SSCs to be protected from the postulated piping failures.

3.6.1 Plant Design for Protection Against Postulated Piping Failures in Fluid Systems Inside and Outside Containment

3.6.1.1 Design Bases

The BWRX-300 pipe break event protection complies with GDC 4. The design bases and criteria for the analysis required to demonstrate that essential SSCs are protected from piping failure is provided in Branch Technical Position (BTP) 3-3 “Protection Against Postulated Piping Failures in Fluid Systems Outside Containment,” and BTP 3-4, “Postulated Rupture Locations in Fluid System Piping Inside and Outside Containment.” BTP 3-4 describes criteria for selecting the locations and orientations of postulated breaks and cracks in fluid systems piping.

3.6.1.1.1 Break Exclusion Zone

The break exclusion zone typically runs from the inboard Containment Isolation Valve (CIV) through the containment penetration to the outboard CIV as described in BTP 3-4 B.1(ii). Those sections of piping systems in containment penetration areas that meet the augmented requirements for a break exclusion zone in accordance with BTP 3-4, are exempted from the evaluation of the dynamic effects of postulated breaks in high energy piping, and the installation of the corresponding whip restraints and jet shields. The dynamic effects that are eliminated are:

- Pipe whip
- Jet impingement
- Blast wave
- Blowdown (decompression water hammer)

In the BWRX-300 design, the Reactor Isolation Valve (RIV) is acting as the inboard CIV for all high energy systems subjected to BTP 3-4 B.1(ii) criteria. The boundaries of the break exclusion zone run from the piping weld at the flanged connection to RIVs (inboard CIVs) to the outboard CIVs and past the outboard CIVs to the seismic interface restraints. As discussed in NEDC-33911P-A, “BWRX-300 Containment Performance,” (Reference 3.6-1), the Isolation Condenser System (ICS) does not have an outboard CIV and all of the ICS piping is within the break exclusion zone. Exclusion of breaks from the flanged connection to the Reactor Pressure Vessel (RPV) is discussed in Chapter 5.

Section 5.1.7 of NEDC-33911P-A discusses the break exclusion zone boundaries where breaks and cracks are postulated in those portions of piping from the RIVs that function as the inboard CIVs to the containment wall. NEDC-33910P-A, “BWRX-300 Reactor Pressure Vessel Isolation and Overpressure Protection,” (Reference 3.6-2) discusses that each RIV is also connected to the outboard piping using bolted flange connections. Section 2.4.1 of NEDC-33910P-A discusses that for piping connected to the RIV extending to the containment wall, the BWRX-300 design requirements include identifying postulated pipe rupture locations and configurations inside containment as specified in BTP 3-4, B.1(iii)(2), and identifying leakage cracks as specified in BTP 3-4, B.1(v)(2). Additionally, NEDC-33910P-A states that a terminal end break would be postulated at the piping connection to the reactor pressure vessel outboard isolation valve as specified in BTP 3-4, B.1(iii)(2).

However, for the piping in containment penetration areas, breaks and cracks are not postulated in portions of piping from the piping weld to the RIV flange up to and including the nearest seismic restraint outboard of the outside CIV as discussed above. This approach is acceptable as all requirements from BTP 3-4 B.1(ii) are met for the BWRX-300 design, which allows eliminating postulated breaks and cracks in those portions of piping within the containment penetration areas from the containment wall to the inboard or outboard CIVs.

The USNRC Safety Evaluation Report for NEDC-33911P-A (Reference 3.6-1) has a limitation and condition specified in Section 6 which states “USNRC staff must review and approve in future licensing activities the potential postulated breaks and cracks in the closed-loop piping being used for meeting GDC 55 on the “other defined basis.” In addition, the USNRC staff reviews the consequences of pipe failures outside containment resulting from the ICS steam supply and condensate return piping and Fine Motion Control Rod Drive (FMCRD) hydraulic lines. The evaluation includes dynamic and environmental effects of pipe failures and fission product releases in the reactor building.”

The FMCRD hydraulic lines evaluation includes dynamic and environmental effects of pipe failures. However, for the BWRX-300 design, the piping within the ICS component jurisdiction is considered as a break exclusion zone. This approach is acceptable as all requirements from BTP 3-4 B.1(ii) are met for the BWRX-300 design which allows eliminating postulated breaks and cracks in those portions of piping within the containment penetration areas from the containment wall to, the inboard or outboard CIVs.

3.6.1.1.2 Environmental Effects in Break Exclusion Zone

BTP 3-3 B.1(a)(1) specifies: “Even though portions of the main steam and feedwater lines meet the break exclusion requirements of item 2.A(ii) of BTP 3-4, they should be separated from essential equipment. Designers are cautioned to avoid concentrating essential equipment in the break exclusion zone. Essential equipment must be protected from the environmental effects of an assumed non-mechanistic longitudinal break of the main steam and feedwater lines. Each assumed non-mechanistic longitudinal break should have a cross sectional area of at least one square foot and should be postulated to occur at a location that has the greatest effect on essential equipment.”

Non-mechanistic longitudinal breaks are postulated in the main steam and main feedwater piping at the location having the most adverse effect on essential SSCs for evaluation for environmental, flooding, and over-pressure damage. A flow area of 1.0 ft^2 (0.0929 m^2) in BTP 3-3 B.1(a)(1) is applicable to large, light-water reactors but is disproportionately large for a small modular reactor with small pipe sizes. Therefore, the flow area will be proportionally scaled to reflect the smaller main steam and feedwater pipe size in the BWRX-300 design and provided in the FSAR.

3.6.1.1.3 Augmented Inservice Inspections

In accordance with BTP 3-4 B.1(ii)(7), “A 100 percent volumetric inservice examination of all pipe welds should be conducted during each inspection interval as defined in American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code, Section XI, IWA-2400.” The welds and base metal in the break exclusion zone are pre-examined and subject to Inservice Inspection (ISI) in accordance with ASME Boiler and Pressure Vessel Code (BPVC, Section XI, Division 1, “Rules for Inspection and Testing of Components of Light-Water-Cooled Plants,” (Reference 3.6-3). The ISI is performed on 100% of the welds during each Inspection Interval.

The break exclusion zone piping is assessed for the potential of damage mechanisms other than weld cracking. The break exclusion zone specific damage mechanisms are identified, based on industry data, including using the latest revisions of:

- NUREG-1801 “Generic Aging Lessons Learned”
- NUREG-2191 “Generic Aging Lessons Learned for Subsequent License Renewal”

The break exclusion zone piping is systematically assessed for all the potentially applicable Generic Aging Lessons Learned damage mechanisms (NUREG-1801 and NUREG-2191), and operational experience such as published by Electric Power Research Institute (EPRI), and the corresponding augmented inspections are developed. These augmented inspections are an essential part of assuring that piping in the break exclusion zone is not subjected to leakage or rupture. The ISI are implemented using Non-Destructive Examination (NDE) techniques that have been demonstrated and qualified to detect threshold values of metal loss, cracking, or embrittlement as part of the break exclusion zone ISI procedure. The break exclusion zone piping is designed and laid out to provide access for ISI of every pipe segment, bend, and weld. The break exclusion zone piping is subjected to augmented pre-operational testing for evidence of vibration, in accordance with ASME OM Code, “Operation and Maintenance of Nuclear Power

Plants," (Reference 3.6-4). Initial ISI programs use the latest edition of ASME BPVC, Section XI (Reference 3.6-3) and the ASME OM Code subject to the conditions identified and incorporated by reference into 10 CFR 50.55a, 18 months before the date of issuance of the Operating License and is addressed in the FSAR.

3.6.1.1.4 Guard Pipe Assembly Design Criteria

In accordance with NUREG-0800, BTP 3-4, B.1.(ii)(3), where guard pipes are used, the enclosed portion of fluid system piping utilizes seamless construction without circumferential welds unless specific access provisions are made to permit inservice volumetric examination of the longitudinal and circumferential welds.

Guard pipes provided for those portions of piping in the containment penetration areas are designed in accordance with the criteria of the ASME BPVC, Section III, Subsection NE, "Class MC Components," where the guard pipe is part of the containment boundary. In addition, the guard pipe assembly is designed to meet the following design criteria and tests specified in BTP 3-4, B.1.(ii)(6):

1. The design pressure and temperature are not less than the maximum operating pressure and temperature of the enclosed pipe under normal plant conditions.

2. The Level C stress limits in NE-3220 are not exceeded under the loading associated with containment design pressure and temperature in combination with the Safe Shutdown Earthquake (SSE).

3. Guard pipe assemblies are subjected to a single pressure test at a pressure not less than its design pressure.

4. Guard pipe assemblies do not prevent the access necessary to conduct the inservice examination specified in BTP 3-4, 2.A(ii)(7). Inspection ports, if used, are not located in that portion of the guard pipe through the annulus of dual barrier containment structures.

3.6.1.1.5 Protection of Essential Structures, Systems, and Components

The design of the plant provides adequate general protection against postulated high energy and moderate energy fluid system pipe ruptures, to the extent necessary to ensure the integrity and operability of essential SSCs required to safely shut down the plant and mitigate the consequences of the postulated piping failure in accordance with regulatory requirements. Both direct dynamic effects on essential SSCs inside the zone of influence and indirect dynamic effects are considered. Examples of an indirect effect would be the whipping pipe impacting a structural frame to which essential SSCs are attached, dislodged grating resulting in a secondary missile, or missiles from back face scabbing or front face spalling on reinforced concrete caused by pipe impact.

SRP Subsections 3.6.1 and 3.6.2 describe acceptable measures that could be taken for protection against the breaks and cracks and for restraint against pipe whips that result from breaks as discussed in Subsection 3.6.1.3.

If the consequence of dynamic effects on essential SSCs is unacceptable, the following mitigation options may be applied:

1. The essential SSCs are relocated.

2. The whipping pipe is restrained by a whip restraint, resulting in a smaller restrained zone of influence that does not encompass the essential target.

3. A protective barrier or jet shield is used to protect the essential SSCs from impact (barrier) or jet impingement (barrier or jet shield).

4. The essential SSCs are qualified to operate following the pipe rupture interaction.

3.6.1.2 Definition of High Energy and Moderate Energy Fluid Systems

High Energy Fluid Systems are defined as those systems or portions of systems that, during normal plant conditions are either in operation or are maintained pressurized under conditions where either or both of the following are met:

- Maximum operating temperature exceeds 95°C (200°F)
- Maximum operating pressure exceeds 1900 kPa (275 psig)

Systems or portions of systems pressurized above atmospheric pressure during normal plant conditions that are not classified as high energy are classified as Moderate Energy Fluid Systems.

Through-wall leakage cracks in lieu of breaks are postulated in the piping of those fluid systems that qualify as high energy fluid systems for only a short operational period but qualify as moderate energy fluid systems for the major operational period. An operational period is considered “short” if the fraction of time that the system operates within the pressure-temperature conditions specified for high energy fluid systems is less than 2% of the time that the system operates as a moderate energy fluid system.

For the BWRX-300, the following high energy piping systems are considered as potential candidates for a postulated pipe break during normal plant conditions and are analyzed for potential damage resulting from damage effects:

- Nuclear Boiler System
- Isolation Condenser System
- Control Rod Drive System
- Reactor Water Cleanup System
- Condensate and Feedwater Heating System
- Offgas System
- Condensate Filters and Demineralizers System
- Moisture Separator Reheater System
- Main Condenser and Auxiliaries

Moderate energy piping systems considered as potential candidates for a postulated pipe crack include the following:

- Boron Injection System
- Isolation Condenser Pools Cooling and Cleanup System
- Shutdown Cooling System
- Fuel Pool Cooling and Cleanup System
- Liquid Waste Management System
- Turbine Bypass System
- Circulating Water System
- Chilled Water Equipment
- Plant Cooling Water System
- Plant Pneumatics System
- Passive Containment Cooling System
- Containment Inerting System
- Containment Cooling System
- Heating, Ventilation, and Cooling System
- Fire Protection System
- Equipment and Floor Drain System
- Water, Gas, and Chemical Pads

3.6.1.3 Design (Safety) Evaluation

Essential SSCs are protected against postulated piping failures. The effects of postulated breaks and cracks include pipe whipping, jet impingement, fluid decompression waves within the ruptured pipes and environmental effects such as temperature, pressure, humidity, chemical exposure, radiation, spray wetting, flooding, and subcompartment pressurization.

An evaluation is performed to verify that the consequences of failures of high and moderate energy lines do not affect the ability to safely shut down the plant. Analysis of the postulated failure of piping is provided during the Operating Licensing review process.

3.6.2 Determination of Rupture Locations and Dynamic Effects Associated with the Postulated Rupture of Piping

Information concerning break and crack location criteria and methods of analysis for dynamic effects are discussed in this subsection in accordance with NUREG 0800, SRP 3.6.2. This includes location criteria and methods of analysis needed to evaluate the dynamic effects associated with postulated breaks and cracks in high and moderate energy fluid system piping inside and outside of the primary containment. The information in this subsection provides the basis for the requirements for the protection of essential SSCs.

3.6.2.1 Criteria Used to Define Break and Crack Location and Configuration

The following subsections establish the criteria for the location and configuration of postulated breaks and cracks.

3.6.2.1.1 Locations of Postulated Pipe Breaks

Postulated pipe breaks are selected as follows:

Piping in the Containment Penetration Areas

Because the augmented requirements of BTP 3-4 are implemented, the dynamic effects resulting from the postulation of guillotine breaks in high energy lines in containment penetration areas are excluded from the design.

ASME BPVC Section III Class 1 Piping in Areas Other Than Containment Penetration

Pipe breaks are postulated at the following locations in each piping and branch run designed in accordance with the criteria provided in ASME BPVC, Section III, Division 1, “Rules for Construction of Nuclear Facility Components,” Subsection NB, “Class 1 Components,” (Reference 3.6-5):

- At terminal ends
- At intermediate locations where the maximum stress range or fatigue usage values exceed the limits specified in BTP 3-4

ASME BPVC Section III Class 2 and 3 Piping in Areas Other Than Containment Penetration

Pipe breaks are postulated at the following locations in those portions of each piping and branch run designed in accordance with the design criteria provided in ASME BPVC, Section III, Division 1, “Rules for Construction of Nuclear Facility Components,” Subsection NCD, “Class 2 and 3 Components,” (Reference 3.6-6):

- At terminal ends
- At intermediate locations where the maximum stress values exceed the limits specified in BTP 3-4

Non-ASME BPVC Section III Piping

Breaks in seismically analyzed high energy non-ASME BPVC Section III piping are postulated according to the same criteria as for ASME BPVC, Section III, Class 2 and 3 high energy piping systems.

Breaks in non-seismically analyzed high energy non-ASME BPVC Section III piping are postulated at terminal ends and at each intermediate location such as pipe fittings, valves, flanges, and welded attachments.

3.6.2.1.2 Locations of Postulated Pipe Cracks

Postulated pipe crack locations are selected as follows:

Piping in Containment Penetration Areas

Regions of high and moderate energy piping associated with containment penetrations consider analytical concepts to eliminate the need to consider postulated cracks as described in BTP 3-4.

ASME BPVC Section III Class 1, 2, 3 and non-ASME BPVC Section III High Energy Piping in Areas Other Than Containment Penetration Areas

Cracks in high energy piping are postulated as follows:

1. For ASME Class 1 piping at axial locations where the calculated stress range values exceed the limits specified in BTP 3-4.

2. For ASME Class 2 and 3 or non-ASME BPVC Section III piping at axial locations where the calculated stress values exceed the limits specified in BTP 3-4.

3. For non-seismically analyzed non-ASME BPVC Section III piping which has not been evaluated to obtain stress information, through-wall cracks are postulated at axial locations that produce the most severe environmental effects.

ASME BPVC Section III Class 1, 2, 3 and non-ASME BPVC Section III Moderate Energy Piping in Areas Other Than Containment Penetrations

Cracks in moderate energy piping adjacent to essential SSCs are postulated except where:

1. For ASME Class 1 piping, the calculated stress range values are less than the limits specified in BTP 3-4.

2. For ASME Class 2 or 3 and non-ASME BPVC Section III piping, the calculated stress values are less than the limits specified in BTP 3-4.

Through-wall cracks, unless the piping system is exempted above, are postulated at axial and circumferential locations that result in the most severe environmental effects.

3.6.2.1.3 Types of Breaks and Cracks to be Postulated

Pipe Breaks

Where not precluded by other means, the following criteria are used to postulate breaks in high energy fluid system piping at the identified locations:

1. Circumferential breaks are postulated in piping having a diameter nominal greater than DN25 (1-inch nominal pipe size).

2. Longitudinal breaks are postulated only in piping having a nominal diameter greater than DN100 (4-inch nominal pipe size).

3. Longitudinal breaks are not postulated at terminal ends.

4. For stress related breaks, if the maximum stress range in the axial direction is at least 1.5 times the circumferential for the most severe loading combination associated with Level A and Level B service limits, a longitudinal break need not be postulated. Conversely, if the maximum stress range in the circumferential direction is at least 1.5 times the stress range in the axial direction for the most severe loading combination associated with Level A and Level B service limits, a circumferential break need not be postulated.

5. Circumferential breaks are perpendicular to the pipe axis, and the break area is equivalent to the internal cross-sectional area of the ruptured pipe. Dynamic forces resulting from such breaks are assumed to separate the piping axially, and cause whipping in any direction normal to the pipe axis.

6. Longitudinal breaks are assumed to result in an axial split without pipe severance. Splits are oriented (but not concurrently) at two diametrically opposed points on the piping circumference such that the jet reactions cause out-of-plane bending of the piping configuration. The longitudinal break area is equal to the pipe flow area.

Pipe Cracks

Where applicable, the following criteria are used to postulate through-wall leakage cracks in high or moderate energy fluid system piping at the identified locations:

1. Leakage cracks are postulated only in piping having a diameter nominal greater than DN25 (1-inch nominal pipe size).

2. Crack openings are assumed as a circular orifice of area equal to that of a rectangle having dimensions one-half pipe diameter in length and one-half pipe wall thickness in width.

3. The flow from the crack opening is assumed to result in an environment that wets all unprotected components within the compartment, with consequent flooding in the compartment and communicating compartments, based on a conservatively estimated time period to effect corrective actions.

3.6.2.2 Analytical Methods to Define Forcing Functions and Response Models

3.6.2.2.1 Analytical Methods to Define Blowdown Forcing Functions

Thrust force and its magnitude, which are determined at the postulated circumferential and longitudinal break, are developed by analytical solutions (closed-form equations) or by numerical simulation (computational fluid dynamics techniques). Analytical methods used to establish pipe rupture blowdown and jet thrust forcing functions are in accordance with American National Standards Institute/ American Nuclear Society (ANSI/ANS) 58.2, “Design Basis for Protection of

Light Water Nuclear Power Plants Against the Effects of Postulated Pipe Rupture," Appendix B, (Reference 3.6-7) modified by NUREG/CR-7275, "Jet Impingement in High-Energy Piping Systems," to address SRP 3.6.2, Appendix A, conservative pressure source terms.

3.6.2.2.2 High Energy Pipe Whip Analysis

The analysis of pipe whip follows analytical methods using dynamics equations or a numerical method using computational fluid dynamics and/or finite element analysis. The following are some of the considerations that apply to pipe whip analysis:

- Two ends of the broken pipe move clear of each other unless physically limited by piping restraints, structural members, or piping stiffness.
- Determine the direction of the thrust force, axial to the broken pipe segment (perpendicular to the break area).
- The unrestrained zone of influence is determined in the direction of the jet reaction initially, with the total path controlled by the piping geometry.
- If unrestrained, a whipping pipe having a constant energy source sufficient to form a plastic hinge is considered to form a plastic hinge and rotate about the plastic hinge or the nearest rigid pipe whip restraint, anchor, or wall penetration capable of resisting the pipe whip loads; or rotate about the calculated dynamic plastic hinge location.
- Where the hinge moment has a torsional and a bending component, the hinge does not result in a planar unrestrained zone of influence. In this case, a half-sphere unrestrained zone of influence is assumed with the pipe sweeping a 180° arc from its initial position to its final resting position, unless a more detailed analysis is performed to justify a smaller unrestrained zone of influence.
- If the plane of motion of a whipping pipe is normal to a flat surface at impact, it is assumed that the pipe comes to rest against that surface.
- The internal fluid energy level associated with the pipe break reaction considers any line restrictions (e.g., flow limiter) between the pressure source and break location, and the effects of either single-ended or double-ended flow conditions, as applicable. The energy level in a whipping pipe is considered insufficient to rupture an impacted pipe of equal or greater nominal pipe size and equal or heavier wall thickness.
- Credit is taken for the limited amount of energy in closed ended piping runs near dead ends or normally closed valves.
- For those portions of high energy piping systems that are normally pressurized only during plant conditions other than 100% power, the thermodynamic state that produces the most severe fluid reaction forces is used.

3.6.2.3 Dynamic Analysis Methods to Verify Integrity and Operability

3.6.2.3.1 Jet Impingement Analyses

Modeling of the jet geometry and determination of the jet impingement force acting on a target is calculated according to ANSI/ANS 58.2, with modifications applied as identified in NUREG/CR-7275.

3.6.2.3.2 Design Codes and Load Combinations for Pipe Whip Restraint

Pipe whip restraints are Seismic Category II. They are seismically designed to prevent adverse interaction with Seismic Category I SSCs. Pipe whip restraints are designed to the following codes and standards:

- Pipe whip restraints that only act to restrain the effects of pipe breaks, and are not active for other loads, are designed to ANSI/American Institute of Steel Construction (AISC) N690-18, “Specification for Safety-Related Steel Structures for Nuclear Facilities,” (Reference 3.6-8). They are not designed to ASME BPVC, Section III, Division 1, “Rules for Construction of Nuclear Facility Components,” Subsection NF, “Supports.”
- Pipe whip restraints that also act as restraints for other loads (e.g., deadweight, seismic) are designed to ASME BPVC, Section III, Subsection NF, (Reference 3.6-9). However, the qualification for the pipe break impact load follows ANSI/AISC N690-18.
- The pipe whip restraints are designed to allow access for ISIs. The measures taken for the protection of essential SSCs do not preclude the conduct of inservice examinations of pressure-retaining components as required by the rules of ASME BPVC Section XI.
- The pipe-restraint gap is sufficiently small to limit the kinetic energy of the whipping pipe and therefore the impact load.
- The pipe-restraint gap is sufficiently large to prevent interference from thermal expansion of the line.
- Pipe whip restraints are located to prevent the formation of a plastic hinge.

The pipe whip restraints, jet shields, and barriers are designed for the following load and load combinations (Service Level D):

$$DW + TH + \sqrt{DBPB^2 + (|SSE| + |SSES| + |SWE|)^2}$$

Where:

DBPB = Design Basis Pipe Break (including jet impingement)

DW = Deadweight

SSE = Safe Shutdown Earthquake

SSES = SSE seismic anchor motion of the restraint structure

SWE = Seismic Self-Weight excitation of the restraint structure

TH = thermal loads due to the expansion of the whip restraint relative to the post-break hot building structure.

3.6.2.4 Analytical Methods to Define Blast Wave Interaction to Essential SSCs

Blast Wave Effects

- High energy blast wave analysis is performed assuming the break opening time as instantaneous, maximizing blast formation.
- The formation and effects of a blast wave caused by a High Energy Line Break (HELB) is evaluated using three-dimensional computational fluid dynamics modeling technique that reflects the thermo-hydraulic parameters at the instant of the postulated pipe rupture, within 1 millisecond of the onset of the break.
- These blast wave forces on target surfaces are impulsive loads that last a few milliseconds or less.
- The blast analysis includes amplification caused by blast wave reflections against walls, and the effects of angled incidence.
- Because of pressure-relieving clearing at the edges of a target surface, and the short duration of the pressure impulse, small structures are not exposed to significant loading. The analysis of blast wave effect is therefore limited to walls, floors, and large vessels.
- Blast force and impulse may be bounded by the jet thrust forces that subsequently develop.

3.6.2.5 Pipe Break Analysis Results and Protection Methods

A summary of the dynamic analyses applicable to high energy piping systems follows the guidelines provided in NUREG 0800, SRP 3.6.2. This information is provided and completed in conjunction with the Operating License application process.

3.7 Seismic Design

The seismic design of the BWRX-300 Structures, Systems, and Components (SSCs) complies with GDC 2, “Design Bases for Protection Against Natural Phenomena,” as stated in Section 3.1 and 10 CFR 50, Appendix S, “Earthquake Engineering Criteria for Nuclear Power Plants.”

The SSCs are assigned a seismic category that reflects their functional and performance requirements during or after a seismic event and affects their design.

Seismic Category I SSCs required to remain functional during and after a seismic event are seismically qualified to withstand the effects of a Safe Shutdown Earthquake (SSE). This SSE is developed following the guidance of RG 1.208, “A Performance-Based Approach to Define the Site-Specific Earthquake Ground Motion,” and is based on the results of the site investigations discussed in Section 2.5. Subsection 3.7.1 provides the site-specific SSE ground motions used for the seismic design and qualification of the BWRX-300 plant, along with other design parameters developed for the seismic analysis.

Table 3A-1 provides the seismic categorization of the BWRX-300 systems and components. The seismic categorization of the BWRX-300 Power Block structures is presented in Table 3A-2.

As listed in Table 3A-2, the containment structure, the containment internal structures, and the Reactor Building (RB) enveloping them are the only civil structures categorized as Seismic Category I.

The Radwaste Building (RWB) which processes and houses liquid, solid, and gaseous highly radiological waste is categorized as Seismic Category RW-IIa per RG 1.143, “Design Guidance for Radioactive Waste Management Systems, Structures, and Components Installed in Light-Water-Cooled Nuclear Power Plants,” and is designed for 1/2 SSE. The RWB is adjacent to and can interact with the RB during seismic or extreme wind events. The seismic interaction evaluation of the RWB is performed following the requirements and guidelines in Section 6.2 of NEDO-33914-A, “BWRX-300 Advanced Civil Construction and Design Approach,” (Reference 3.7-1) to ensure the structural integrity and safety functions of the RB Seismic Category I SSCs are not compromised.

The Control Building (CB), Turbine Building (TB), Service Building, and Reactor Auxiliary Structures (see Section 1.2) support or protect SSCs that are not credited in the safety analysis or that can perform their desired function regardless of structure performance. These structures also have the potential to interact with the RB during seismic or extreme wind events due to their proximity to the RB. As a result, the structures are assigned the BWRX-300 Seismic Category II described in Section 3.2 and are designed in accordance with the International Building Code (IBC) (Reference 3.7-2). The seismic interaction evaluation of the structures with the RB is performed following the requirements and guidelines in Section 6.2 of NEDO-33914-A.

The remaining Power Block structures consisting of detached pre-fabricated/modularized Equipment Structures are categorized as Non-Seismic and are designed per the IBC.

Table 3.7-1 summarizes the seismic design basis for the Power Block structures based on their seismic categories. As indicated in Table 3.7-1, the seismic design of Seismic Category I structures considers Limit State LS-D response defined in Table 1-1 of American Society of Civil Engineers (ASCE)/Structural Engineering Institute (SEI) 43, “Seismic Design Criteria for Structures, Systems, and Components in Nuclear Facilities,” (Reference 3.7-3) as essentially elastic response. As explained in RG 1.208, this ensures a consistent level of safety from earthquake-caused failures defined by level of response resulting in an onset of significant inelastic deformations with a probability of unacceptable performance:

- Less than 1% for an SSE ground motion level
- Less than 10% for ground motion with 1.5 times the SSE intensity

Analyses performed to qualify the Seismic Category I structures are discussed in Subsection 3.7.2. Analyses performed to qualify the Seismic Category I subsystems are discussed in Subsection 3.7.3. The interaction of Non-Seismic Category I SSCs with Seismic Category I SSCs is addressed in Subsections 3.7.2.8 and 3.7.3.8. Seismic instrumentation used to monitor earthquake events, and their effects are discussed in Subsection 3.7.4. For more information on the design of the RWB, refer to Subsection 3.8.4.3.

In the following subsections, reference to the integrated RB is inclusive of the RB, containment, and containment internals, whereas RB is used to refer to the reactor building structure outside of containment.

3.7.1 Seismic Design Parameters

3.7.1.1 Design Ground Motion

The BWRX-300 design considers Operating Basis Earthquake (OBE) and SSE design ground motions following the guidance of SRP 3.7.1, “Seismic Design Parameters.”

Subsections 3.7.1.1.1 and 3.7.1.1.2 present the SSE design response spectra and time histories used for the design of the BWRX-300 Seismic Category I SSCs at the Clinch River Nuclear (CRN) Site.

The OBE at the CRN Site is set as 1/3 of the SSE. In accordance with Appendix S to 10 CFR 50 and SRP 3.7.1, design load combinations that consider OBE loads are not required except for the design of containment metal components. OBE loads are considered for post-flooding condition and cyclic loading considerations for the containment metal components following the guidance of SRP 3.8.2, “Steel Containment.” The use of OBE for plant shutdown is discussed in Subsection 3.7.4.4.

Fatigue evaluation criteria for seismic subsystems are addressed in Subsection 3.7.3.2 and Sections 3.9 and 3.12.

3.7.1.1.1 Design Response Spectra

The ground motion design spectra presented in this subsection define the amplitude and the frequency content of the design ground motion used for the seismic design of the BWRX-300 at the CRN Site. The ground motion design spectra are developed based on the results of the Probabilistic Seismic Hazard Assessment (PSHA) discussed in Section 2.5, considering as-built subgrade conditions consisting of engineered backfill on top of the existing fill, in-situ residual soil, weathered rock and base rock. The SSE ground motion design spectra are developed in accordance with SRP 3.7.1 and RG 1.208, using the performance-based approach of ASCE/SEI 43-19and the additional requirements provided in Section 5.2.2 of NEDO-33914-A.

In accordance with the requirements of Section 5.2.2 of NEDO-33914-A, the following horizontal and vertical spectra define the CRN site-specific SSE ground motion:

1. Foundation Input Response Spectra (FIRS) defining the SSE ground motion at the bottom of the integrated RB foundation.

2. Performance Based Surface Response Spectra (PBSRS) defining the SSE ground motion at the finished plant grade elevation.

3. Performance Based Intermediate Response Spectra (PBIRS) defining the SSE ground motion at intermediate embedment depth elevation established, following the guidelines in Section 5.2.2 of NEDO-33914-A, at the top of the rock elevation having a significant contrast between rock and overlaying soil shear wave velocities.

The purpose of PBIRS is to ensure the ground motions used as input for the Soil-Structure Interaction (SSI) analyses of deeply embedded integrated RB are adequate throughout the depth of the embedment.

The 5% damped horizontal FIRS, PBSRS and PBIRS are obtained from the probabilistic Site Response Analysis (SRA) results as discussed in Subsection 2.5.2. Figure 2.5.2-93R presents the horizontal FIRS, PBSRS and PBIRS developed for the BWRX-300 at the CRN Site.

The vertical FIRS, PBSRS and PBIRS for the BWRX-300 at the CRN Site are developed by applying Vertical to Horizontal (V/H) ratios calculated using Pezeshk et al. V/H model (Reference 3.7-4) to the horizontal spectra. Table 2.5.2-40 presents the rock and soil V/H ratios used for calculation of the vertical ground motion design spectra.

The Nuclear Energy Institute (NEI) checks are performed following the procedure described in Section 5.3.4.1 of NEDO-33914-A to ensure the ground motion used as input for the deterministic SSI analyses of the deeply embedded integrated RB at its foundation bottom elevation meets the guidance of DC/COL-ISG-017, “Ensuring Hazard-Consistent Seismic Input for Site Response and Soil Structure Interaction Analyses,” to be hazard consistent with the results of the probabilistic SRA. The NEI check requires that the PBSRS be enveloped by the FIRS propagated upward through the three strain-compatible soil profiles used as input for the

SSI analyses, presented in Subsection 3.7.1.3. When the enveloped Acceleration Response Spectra (ARS) of the propagated motion do not meet or exceed the PBSRS, the FIRS are augmented until the augmented input ground motion satisfies the NEI check.

To ensure the propagated SSI foundation input motions envelop the horizontal and vertical PBSRS, the frequency dependent factors shown in Figure 3.7-1 are used to augment the FIRS. As shown in Figure 3.7-2, which presents the NEI check of the augmented horizontal and vertical FIRS, the envelope of the 5% damped spectra for the responses at the surface of the Lower Bound (LB), Best Estimate (BE) and Upper Bound (UB) profiles do not fall below the PBSRS. This confirms that the DC/COL-ISG-017 requirement is met.

Figure 3.7-3 presents the augmented ground motion spectra defining the amplitude and frequency content of the horizontal and vertical SSI input control motion applied to the SSI model at the RB foundation bottom. Figure 3.7-4 and Figure 3.7-5 present the PBIRS at the top of the un-weathered rock layer and the PBSRS at the finished plant grade elevation, respectively.

The derived horizontal and vertical FIRS envelop the spectra from RG 1.60, “Design Response Spectra for Seismic Design of Nuclear Power Plants,” anchored at 0.1 g, as required by Appendix S to 10 CFR Part 50 and demonstrated in Figure 3.7-3.

3.7.1.1.2 Design Time Histories

Design ground motion Acceleration Time Histories (ATH) used as input to the seismic SSI analyses of the integrated RB at the CRN Site are developed by spectral matching seed ground motion records to the ground motion design response spectra presented in Figure 3.7-3. In accordance with Section 5.2.3 of NEDO-33914-A, five sets of three design motion ATHs, in the two horizontal and in the vertical directions, are developed for the design to mitigate uncertainties due to the phasing of the time history frequency components. This number of design ground motion ATHs exceeds the minimum of four allowed in NUREG/CR-5347, “Recommendations for Resolution of Public Comments, Seismic Design Criteria.”

Design ATHs are developed by fitting recorded seed time histories to the 5% damped target design spectra. Developed ATHs meet the acceptance criteria for Option 2 in Section II.1.B of SRP 3.7.1, Appendix F of RG 1.208, and the additional guidance of Section 5.2.3 of NEDO-33914-A.

Table 3.7-2 provides details of the selected five sets of time history records used for the development of the design ATHs for the SSI analyses of the BWRX-300 integrated RB at the CRN Site. These are selected from the NGA-West2 ground motion database maintained by the Pacific Earthquake Engineering Research Center (Reference 3.7-5). In accordance with NEDO-33914-A guidance, the selected seed time histories include records with different magnitude and distance bins that have spectral shapes reasonably consistent with the spectral shape of the design target spectrum over the frequency range of interest and characteristics that reasonably represent the earthquake motions expected at the CRN Site.

Using the seed time histories in Table 3.7-2, time histories compatible to the design ground motion spectra in Figure 3.7-3 are generated using the time domain spectral matching method, “An Improved Method for Nonstationary Spectral Matching,” (Reference 3.7-6), where adjustment of initial time histories (seed motions) is made by adding wavelet functions to the initial acceleration time history in time domain. This adjustment is repeated until its spectrum becomes compatible with the target spectrum over the desired frequency range. In accordance with Section 5.2.3 of NEDO-33914-A, the time step of the modified time histories is refined to 0.0025 seconds for the purposes of accurately calculating high frequency in-structural responses.

Response spectra of the generated ATHs are computed at a minimum of 100 points per frequency decade, uniformly spaced over the log frequency scale, and compared to the appropriate target response spectra. Cross-correlation coefficients, peak values, arias intensity, and power spectrum density functions are then computed for the spectrally matched time histories to ensure the modified ATHs meet the following SRP 3.7.1 and RG 1.208 criteria:

- The time step for the modified time histories are less than 0.005 seconds.
- The average of the scaled response spectra of the five sets of modified ATHs do not fall more than 10% below the target spectrum at any one frequency,
- The modified ATH response spectra do not exceed the target response spectrum at any frequency by more than 30% in the frequency range of interest,
- Power spectrum density functions of the modified ATHs do not have significant gaps in energy at any frequency over the frequency range of interest,
- Modified time histories have typical strong motion durations (defined by 5-75% arias intensity), peak ground acceleration, velocity and displacement, and ratios of peak ground acceleration, velocities and displacements that are generally consistent with characteristics for the magnitude-distance pairs for controlling events considered by the PSHA, and
- The modified ATHs are statistically independent with the directional correlation coefficients between pairs of time histories not exceeding a value of 0.16.

Figure 3.7-6, Figure 3.7-7, and Figure 3.7-8 present examples of comparisons of the 5% damped target spectra and the corresponding scaled response spectra of the modified time histories. Figure 3.7-9 shows for each set of time histories, a smooth power spectrum density calculated as the geometrical mean of the power spectrum density of the two horizontal matched time histories. The plot demonstrates that there are no gaps in the power spectrum density for any of the time histories.

Table 3.7-3 presents the ground motion parameters of the matched time histories for FIRS. These parameters are consistent with the typical values for magnitude and distance range for the controlling earthquake as listed in Table 3-5 of NUREG/CR-6728, “Technical Basis for Revision of Regulatory Guidance on Design Ground Motions: Hazard- and Risk-Consistent Ground Motion Spectra Guidelines,” U.S. Nuclear Regulatory Commission. The correlation coefficient between the two horizontal components for each set of the matched time histories for FIRS are presented in Table 3.7-4.

Figure 3.7-10 through Figure 3.7-24 show the matched time history for the selected records listed in Table 3.7-2 matched to the horizontal and vertical FIRS. These plots demonstrate that the selected acceleration, velocity, and displacements are compatible and do not result in displacement baseline drift in conformance with the guidance of Section 3.7.1, Section II.1.B.

3.7.1.2 Percentage of Critical Damping Values

Table 3.7-5 lists damping values used in the seismic analysis of the integrated RB structures and components. OBE and SSE damping values assigned to the integrated RB structures and components are in accordance with RG 1.61, “Damping Values for Seismic Design of Nuclear Power Plants,” with steel-plate composite damping values being based on the values provided for steel-plate composite walls in Tables 1 and 2 of RG 1.61. Damping values listed in Table 3.7-5 are applicable to all structural elements constructed of the same material.

Damping properties assigned to soil materials in the SSI analysis model take into account the stress-strain properties corresponding to the level of seismic input per the guidance of SRP 3.7.1. To account for the primary non-linearity of the subgrade materials, stiffness and damping properties of subgrade materials compatible to the free-field strains generated by design level earthquake event are developed based on results of Approach 3 SRA discussed in Subsection 2.5.2. The strain-compatible damping of the subgrade materials is limited to 15% in accordance with the regulatory guidance of SRP 3.7.1, RG 1.208, Appendix E and the recommendations of ASCE/SEI 4-16, “Seismic Design of Safety-Related Nuclear Structures,” (Reference 3.7-7), Section C5.2.

Following the guidance of RG 1.61, Section C.1.2, lower OBE damping ratios are assigned to structural elements for generating in-structure demands for seismic qualification of equipment and systems. The higher SSE damping values may be used for development of seismic demands for structural design per ASCE/SEI 43-19, Section 3.3.3 and RG 1.61, Section C.1.2, respectively.

Damping values for seismic evaluations of subsystems including piping and equipment are obtained using the procedures described in Subsection 3.7.3.5.

3.7.1.3 Supporting Media for Seismic Category I Structures

The integrated RB structures are built on a common mat foundation deeply embedded in soil and the rock below. For a description of the supporting media at the CRN Site, refer to Sections 2.4 and 2.5. For the foundation embedment depth and total structural height of the Seismic Category I structures, refer to Figure 1.2-2 and Figure 1.2-3. For the Foundation dimensions, refer to Figure 3.8-8.

To address the uncertainties related to the determination and variation of subgrade conditions, the SSI analysis, presented in Appendix 3C, uses three sets of subgrade profiles representing LB, BE and UB estimates of the subgrade material properties. These profiles are representative of the as-built conditions at the CRN Site. The LB and UB shear wave velocities reflect a

minimum coefficient of variation of each layer properties of 0.5. The design uses an envelope of results from the SSI analysis of BE, LB and UB subgrade profiles to account for the variation and uncertainty in subgrade properties in accordance with Section 5.3 of NEDO-33914-A.

The development of dynamic subgrade profiles considers the soils located below the nominal groundwater table to be fully saturated. The groundwater level considered for the seismic SSI analysis at the CRN Site is Elevation 814.5 ft per Table 2.0-1R. Figure 3.7-25 and Figure 3.7-26 present the strain-compatible shear wave velocity profiles, compression wave velocity and damping ratio profiles used for the seismic analyses of BWRX-300 Seismic Category I structures discussed in Subsection 3.7.2.

3.7.2 Seismic System Analysis

In accordance with the requirements and guidelines of Section 5.0 of NEDO-33914-A, the seismic SSI analyses of the BWRX-300 Seismic Category I integrated RB consider the following effects on its structural integrity, seismic response, and distribution of stress demands:

- Interaction of the deeply embedded RB structure with the surrounding subgrade (SSI)
- Variation in the soil and structural parameters
- Hydrodynamic loads (mass and stiffness)
- Structure-Soil-Structure Interaction (SSSI) with the adjoining RWB, CB, TB, Service Building, and Reactor Auxiliary Structures

To adequately account for the SSI and SSSI effects per guidance of Section 5.1 of NEDO-33914-A, the one-step approach, as defined in Section 3.1.2 of ASCE/SEI 4-16, is implemented for the seismic design of the integrated RB structures. Seismic structural stress demands are obtained directly from the results of SSI analyses performed on models that include Three-Dimensional (3D) Finite Element (FE) representations of the integrated RB and the surrounding subgrade. The surrounding subgrade is represented in the SSI analysis models by layered half-space continuum with equivalent linear elastic stiffness properties and complex damping.

The methodology used to develop the integrated RB 3D FE model used in the seismic SSI analyses is described in Subsection 3.7.2.3.

3.7.2.1 Seismic Analysis Method

The BWRX-300 one-step seismic SSI analysis approach provides demands for the seismic design and qualification of SSCs for all frequencies of interest and adequately addresses the effects of SSSI for the integrated RB with adjacent structures and foundations.

The BWRX-300 seismic analysis approach follows the guidance of Section 5.0 of NEDO-33914-A with a few modifications aimed to represent realistic site, structures and construction conditions described in Subsections 3.7.2.3 and 3.7.2.4. Section 5.0 of NEDO-33914-A addresses current limitations in SRP 3.7.2 when capturing the effects of seismic response and addressing the effects of seismic interaction of the deeply embedded RB structure

with adjacent structures through the subgrade. These issues are identified in Section 1.5.11 of NUREG/CR-7193, “Evaluations of NRC Seismic-Structural Regulations and Regulatory Guidance, and Simulation-Evaluation Tools for Applicability to Small Modular Reactors (SMRs),” as an area of concern for deeply embedded SMRs such as the BWRX-300.

The seismic SSI analyses are performed using the sub-structuring method in Section 5.4 of ASCE/SEI 4-16, and the ACS SASSI (a system for analyses of SSI, see Appendix 3I) computer program to calculate the seismic response of the RB SSI system. The sub-structuring method allows the seismic response of the SSI system to be obtained by subdividing the problem into a series of simple subproblems that can be solved separately. Using the principle of superposition, the results of different sub-analyses are combined to obtain the final solution for the SSI problem. The solution for the seismic response of the integrated RB structures is obtained in the frequency domain for a selected set of frequencies and then interpolated for other frequency points.

The linear elastic SASSI analyses are performed on one-step structural models that accurately represent the geometry and dynamic properties of the integrated RB and its interaction with the subgrade. These structural models have a refined FE mesh that can transmit the entire frequency range of interest for the seismic design of the RB SSCs. These models assume isotropic elastic material properties of structural members and surrounding subgrade and neglect any non-linearity at the soil-structure contact interfaces.

The linear elastic assumption, based on the superposition principal, allows seismic demands obtained from the SASSI analyses to be combined with design demands obtained from other structural analyses in seismic design load combinations.

Far-field interaction nodes are established at the surface of each soil layer through the RB shaft embedment depth to calculate the horizontal and vertical components of the far-field motion in the SSI model. The responses calculated from these far-field interaction nodes are used to monitor the propagation of the input control motion through the RB embedment depth.

To account for the primary non-linearity of subgrade materials, a set of profiles of strain-compatible subgrade properties are used as input for the SSI analysis. These subgrade properties are compatible to the free-field strains generated by SSE level earthquake and are developed based on the results of equivalent linear probabilistic SRA presented in Subsection 2.5.2. The profiles of strain-compatible subgrade properties are presented Subsection 3.7.1.3. The uncertainties related to variation of soil and rock properties are addressed as described in Subsection 2.5.2.5.1.

As described in Subsection 3.7.1.1.2, five sets of three input motion ATHs, corresponding to the three orthogonal directions of motion, are used as input for the seismic analyses to mitigate the uncertainty in the computed responses due to the phasing of the time history frequency components.

Input ground motion ATHs are applied to the SASSI model at the RB foundation bottom elevation as vertically propagating coherent:

- Shear waves for horizontal components of the input motion

- Compression waves for the vertical component of the input motion

The horizontal control motion is applied to the SASSI model in a manner that is consistent with the probabilistic One-Dimensional (1D) SRA approach discussed in Subsection 2.5.2. The requirement of DC/COL-ISG-017 for the ground motion used as input for the deterministic SSI analysis being consistent with the motions used for the probabilistic SRA is met as described in Subsection 3.7.2.4.1.

Uncertainties related to variations of the input SSI parameters and the wave propagation pattern through the CRN Site are addressed by results of sensitivity analyses performed as discussed in Subsection 3.7.2.9, following the guidance in Section 5.3 of NEDO-33914-A.

Design responses are obtained from the analysis of each of the three ground motion components for each of the five sets of ATHs using the methodology described in Subsections 3.7.2.5 and 3.7.2.6. The seismic design demands are calculated as the average of the results obtained from the analyses of the five sets of ATHs. Following the guidance of Section 5.3 of NEDO-33914-A, results of the sensitivity analyses discussed in Subsection 3.7.2.9 are included in the RB seismic design basis when significant exceedances are observed.

3.7.2.1.1 Frequencies of Analysis

The frequencies of analyses are determined following the guidelines of Section 5.3.2 of NEDO-33914-A.

Cutoff frequencies are established based on the largest value required by the following criteria:

1. Twice the highest dominant frequency of the coupled soil structure system, or
2. The highest structural frequency of interest, or
3. The frequency at which the Fourier amplitude of input motion has passed its peak value and has reached 10% of the peak value, and
4. 20 Hz

The value of cut-off frequency determined by the criteria described above is used for the analysis of the stiffest subgrade profile and models with UB structural stiffness properties. The analyses of softer subgrade profiles or reduced structural stiffness properties may use lower values for the cut-off frequency as per the guidance of Section 5.3.2 of NEDO-33914-A.

The frequencies of analysis are selected at sufficiently small frequency intervals. Transfer function amplitude results for responses at the key locations are inspected to detect any numerical anomalies in the interpolated transfer functions (e.g., sharp narrow spikes) that can potentially affect the accuracy of results. If present, the effects of these anomalies in the interpolated transfer function results are evaluated using additional frequencies of analysis to ensure the anomalies in the transfer function interpolations do not affect the accuracy of the calculated responses.

3.7.2.2 Natural Frequencies and Response Loads

Refer to Appendix 3C for the significant natural frequencies and SSE responses of the Seismic Category I structures at the CRN Site.

The seismic responses of the RB at the CRN Site are characterized using the results of the SSI analyses for responses at key structural locations and stress responses of key structural members selected per the guidance provided in Section 5.3.1 of NEDO-33914-A.

3.7.2.3 Procedures Used for Analytical Modeling

The 3D FE model used in the SSI analysis of the integrated RB meets the guidance of SRP 3.7.1, SRP 3.7.2 and RG 1.61. The model also meets the structural modeling requirements of Section 3 of ASCE/SEI 4-16, and the one-step modeling requirements and guidelines of Section 5.1.1 of NEDO-33914-A.

Appendix 3B presents the details of the 3D FE model used in the seismic SSI analysis of the integrated RB. This model consists of the integrated RB structure, the surrounding subgrade, the excavated volume of the subgrade materials replaced by the embedded portion of the RB structure and the near field backfill materials. Certain construction elements of the CRN excavation plan are also included in the integrated RB 3D FE model. These consist of a concrete mud mat under the integrated RB common mat foundation, an annulus of concrete fill adjacent to the RB wall extending the full RB embedment height and a concrete shelf increasing the thickness of concrete fill around the annulus from top of rock to surface. Solid elements are used to model the concrete fill material. The inclusion of the concrete fill deviates from the seismic analysis modeling approach described in Section 5.3.8 of NEDO-33914-A. However, the presence of concrete fill per the CRN excavation plan is expected to affect the seismic response of the RB, especially at elevations above the top of un-weathered rock. Modeling these features results in more realistic seismic response consistent with the guidance of SRP 3.7.2.

The CRN excavation plan considers the use of temporary excavation support for the soil around the RB excavation above top of rock. To assess the effects of the excavation support on the RB seismic response (see Subsection 3.7.2.9.2), additional solid elements are also included in the RB SSI model to model the temporary excavation support. These solid elements are assigned soil material properties for the base case seismic analysis and concrete material properties for the sensitivity analysis discussed in Subsection 3.7.2.9.2.

The integrated RB structure is primarily constructed of Diaphragm Plate Steel-Plate Composite (DP-SC) modules. The DP-SC system has a configuration similar to the conventional steel-plate composite system except that the tie-rods in the conventional steel-plate composite system are replaced by diaphragm plates as described in Section 3.4 of NEDC-33926P, “BWRX-300 Steel-Plate Composite (SC) Containment Vessel (SCCV) and Reactor Building Structural Design,” (Reference 3.7-8).

3.7.2.3.1 Dynamic Finite Element Modeling of Integrated RB

The details of the integrated RB seismic SSI model, also known as the dynamic FE model, are provided in Appendix 3B.

In accordance with SRP 3.7.2, Section II.3.D and Section 3.4.2 of ASCE/SEI 4-16, the integrated RB structural FE model represents masses expected to be present at the time of the earthquake. These include 50% of the specified design live loads, 25% of the specified roof design snow loads and the inertia associated with the hydrodynamic effects of the fluids contained in various pools inside the RB.

The hydrodynamic effects that consist of the impulsive and convective (or sloshing) components are considered in accordance with Section II.1.A of SRP 3.7.2 and following the provisions of Section 3.6.3 of ASCE/SEI 4-16, and Chapter 5 of American Concrete Institute (ACI) 350.3, "Code Requirements for Seismic Analysis and Design of Liquid-Containing Concrete Structures," (Reference 3.7-9). The hydrodynamic mass is included in the model by:

- Distributing the horizontal impulsive fluid mass over the pool walls that are perpendicular to the direction of motion in accordance with the guidelines in ACI 350.3
- Lumping the entire vertical fluid mass on the pool slab bottom

The convective (sloshing) component of the hydrodynamic mass is not explicitly included in the global analysis model because its contribution is small and is associated with very low frequencies insignificant for the overall response. To account for the sloshing hydrodynamic effects, the design considers quasi-static sloshing pressure loads applied on the pool walls in accordance with Section 9.4 of ASCE/SEI 4-16.

Beam and shell elements are used to adequately represent the configuration of all main structural members in the integrated RB, with the steel-plate composite shear walls, slabs, and mat foundation being modeled using thick shell elements. The FE model includes gross discontinuities such as large openings and member eccentricity. Member eccentricity and offsets are accounted for by using rigid beam and shell elements or by appropriately adjusting the properties of the centerline modeled elements to account for the effect of large member offsets.

The integrated RB steel-plate composite structural elements are physically connected with welded connections. The FE model generally utilizes centerline shell element models of the steel-plate composite components where adjacent component elements share nodes at their intersecting lines. This modeling assumption effectively suggests rigid connection behavior.

Spring elements with stiffness properties appropriate to capture the interaction at the soil-structure interface connect the RB structural and subgrade FE models. The results obtained from the contact spring elements serve to:

- Calculate dynamic earth pressures on the below grade RB shaft exterior wall and mat foundation
- Determine whether separation between RB shaft wall and soils occurs under SSE loading as discussed in Subsection 3.7.2.9.4

The evaluation of effects of conditions at the contact interfaces with surrounding subgrade on the RB seismic response is discussed in Subsection 3.7.2.9.

The values of Young's modulus and Poisson's ratio representing the structural material stiffness properties are determined in accordance with the governing design codes in Section 3.8. Stiffness properties are assigned to the steel-plate composite structures in accordance with the guidance of SRP 3.7.2 and the requirements of Section 3.3.2 of ASCE/SEI 4-16.

The effective stiffness for analysis of the thick shell elements representing the steel-plate composite members is developed following the approach in Section 5.5 of NEDC-33926P. The stiffness calculations account for the expected state of stress and level of cracking for different loading conditions during normal operation and accident conditions.

The effects of variation of structural stiffness and damping properties is considered in the modeling of the integrated RB to ensure accuracy of the calculated seismic responses and seismic demands as discussed in Subsection 3.7.2.9.1.

The FE models used for seismic SSI analyses have a sufficiently refined mesh to be capable of transmitting the entire frequency range of interest for the seismic design of the RB SSCs. In accordance with the requirements of Section 5.3.4 of ASCE/SEI 4-16, the FE mesh is smaller than or equal to one-fifth of the smallest wavelength transmitted through the soil model, i.e., the maximum mesh size:

$$d_{max} \leq \frac{V_S}{5 f_{cutoff}}$$

where:

V_S is the shear wave velocity of the transmitting soil material; and

f_{cutoff} is the cutoff frequency of analysis determined as described in Subsection 3.7.2.1.1

The lower boundary of the SSI model is established at a distance that is deeper than at least two times the depth of the RB embedment and at least three times the largest foundation dimension from the bottom of the slab, meeting the guidance of SRP 3.7.2, Section II.4.

3.7.2.3.2 Dynamic Modeling of Subsystems, Components and Equipment

The dynamic properties of subsystems, components, and equipment are included in the integrated RB structural model based on the decoupling criteria of SRP 3.7.2, Section II.3.B as stated in NEDO-33914-A and Section 3.7 of ASCE/SEI 4-16. They depend on the ratios of the mass and first natural frequency of the subsystem, component, or equipment to those of the supporting structure.

To capture the dynamic coupling effects of the Reactor Pressure Vessel (RPV), the dynamic properties of the RPV and its components are represented by a Lumped Mass Stick (LMS) model capable of capturing the significant modes of the RPV seismic response. Procedures used to develop this LMS model are presented in Subsection 3.7.3.3.3. The RPV LMS model is connected to the RB structural model using local spring elements, representing the stiffness of the RPV support skirt and the horizontal stabilizers.

3.7.2.4 Soil-Structure Interaction

The SSI analyses of the Seismic Category I integrated RB are performed per the methodology presented in Subsection 3.7.2.1, for the range of subgrade conditions presented in Subsection 3.7.1.3. These subgrade conditions represent as-built conditions consisting of engineered backfill placed on top of the existing fill, in-situ residual soil, weathered rock, and in-situ base rock as stated in Subsection 3.7.1.1.1. The SSI analysis model described in Subsection 3.7.2.3 does not consider the SSSI effects of the surrounding Power Block structures resting on foundations supported by drilled shafts that transfer the vertical loads from these buildings to the bedrock.

To address the SSSI effects of the surrounding Power Block structures on the deeply embedded RB, SSI analyses are performed on a model combining the integrated RB FE model described in Subsection 3.7.2.3.1 with simplified models of the RWB, CB, TB, Service Building and Reactor Auxiliary Structures representing the dynamic properties of these structures. The SSI analyses are performed for a range of as-built subgrade conditions where the in-situ soil and weathered rock are excavated down to competent rock and replaced with engineered fill up to plant grade Elevation 814.5 ft. Properties assigned to the engineered fill are competent for transferring the vertical loads from the Power Block near surface foundations to the bedrock. The consideration of two different free-field site property conditions for the SSI analyses is an alternative approach adopted to add margin in RB seismic demands to account for the absence of drilled shafts from the analyzed models due to their low design maturity. The combined FE model, input ground motions and subgrade properties used to evaluate the SSSI effects are provided in Appendix 3C.

Sensitivity studies performed to evaluate the effects of parameter variations on the integrated RB responses are discussed in Subsection 3.7.2.9. These sensitivity studies are performed using the SSI model with the adjacent Power Block structures which is considered to be the more representative of the expected actual plant conditions.

The following are key requirements and approaches considered in the seismic SSI analyses to ensure the structural integrity and stability of the deeply embedded RB throughout the life of the plant and to address specifics related to its design and construction.

3.7.2.4.1 Implementation of DC/COL-ISG-017 Guidance

BWRX-300 approaches for meeting DC/COL-ISG-017 guidance and addressing current limitations in DC/COL-ISG-017 related to the seismic analysis of deeply embedded structures, as identified in Section 1.5.8 of NUREG/CR-7193, are described in Section 5.3.4 of NEDO-33914-A.

The intent of DC/COL-ISG-017 is to ensure that the deterministic SSI analysis of the embedded RB structure uses ground motion inputs that are hazard consistent with the results of probabilistic SRA at the foundation bottom elevation and at ground surface.

The consistency between the free-field motion at the bottom of the RB foundation used as input for the deterministic SSI analysis and probabilistic SRA is checked as described in Subsection 3.7.1.1, using the procedure described in Section 5.3.4.1 of NEDO-33914-A.

The augmented and smoothed horizontal and vertical 5% damped spectra presented in Figure 3.7-3 define the amplitude and frequency content of the SSI input control motion applied to the SSI model at the RB foundation bottom that is hazard consistent with the results of the probabilistic SRA.

3.7.2.4.2 Coupling of Soil and Structures

The seismic SSSI of the RB with the adjacent RWB, CB, TB, Service Building, and Reactor Auxiliary Structures is explicitly addressed in the seismic analysis and design as described in Subsection 3.7.2.4.

Coarse FE models representing the dynamic properties of the surrounding buildings and foundations are included in the combined FE model used for evaluating the SSSI effects of the adjacent Power Block structures on the RB. These models are sufficiently refined to capture the global modes of vibration of the RWB, CB, TB, Service Building and Reactor Auxiliary Structures with significant (> 20% per Section 5.3.7 of NEDO-33914-A) modal mass participations in the three orthogonal directions.

Subsection 3.7.2.8 presents the approach for addressing the requirements related to the seismic interaction of the RB with the surrounding RWB, CB, TB, Service Building and Reactor Auxiliary Structures and foundations.

3.7.2.5 Development of In-Structure Responses

In-Structure Response Spectra (ISRS) and ATHs are developed from the seismic analysis to serve as input for the seismic design and evaluation of subsystems, components, and equipment in accordance with Section II of SRP 3.7.3.

3.7.2.5.1 In-Structure Response Spectra

The development of the ISRS follows the guidance of Section II.5 of SRP 3.7.2, RG 1.122, “Development of Floor Design Response Spectra for Seismic Design of Floor –Supported Equipment or Components,” and Section 6.2 of ASCE/SEI 4-16. Equipment structure interaction effects may be considered for the development of ISRS using the guidance in Section 5.3.6 of NEDO-33914-A.

ISRS are developed for required damping levels defining the amplitude and frequency content of in-structure design motion at different locations within the RB, in the two horizontal and the vertical directions.

If the equipment or component is supported by flexible slabs or attached to flexible walls, ISRS are developed considering additional nodal responses that capture the local effects of out-of-plane vibrations of the supporting slab or wall.

In accordance with the requirements of Section 6.2.1.1(a) and (b) of ASCE/SEI 4-16, the ISRS are developed from the calculated nodal in-structure responses by:

1. First combining in the time domain, the three co-direction responses due to the three orthogonal components of seismic input motion as an algebraic sum at each time step and then calculating the ARS of the combined ATHs, or

2. Combining the co-directional ARS results obtained from the analysis with the three orthogonal components of seismic input motion using the Square-Root-of-the-Sum-of-the-Squares (SRSS) method specified in Subsection 3.7.2.6.

The ISRS are developed at small frequency intervals to ensure they are sufficiently close to the peak response frequencies of the supporting structure. To meet the guidance of Section II.5 of SRP 3.7.2, the ISRS are calculated at 301 frequency points equally distributed on the logarithmic scale at the frequency range from 0.1 Hz to 100 Hz.

The ISRS are calculated as an envelope of the results from the seismic design basis SSI analysis of all subgrade profiles. Following the guidance of Section 5.3 of NEDO-33914-A, the enveloping ISRS are increased as described in Subsection 3.7.2.9 to address variations of important parameters. In accordance with RG 1.122 and Section 6.2.3 of ASCE/SEI 4-16, the peaks of the enveloping ARS are broadened by a minimum of +/-15% to address uncertainties related to the modeling of natural frequencies of the supporting structure and the SSI analysis methodology. The sharp valleys between peaks are filled to further account for the uncertainties in subgrade properties.

3.7.2.5.2 In-Structure Acceleration Time Histories

In accordance with the requirements of Section 6.3 of ASCE/SEI 4-16, time histories used in the analysis of subsystems are obtained either:

- Directly from the results of the SSI analysis as time histories of nodal responses at reference of subsystem support locations; or
- By generating synthetic time histories compatible to multi-damping ISRS developed as described in Subsection 3.7.2.5.1.

When obtained directly from the SSI analysis results:

- Time histories of the co-directional in-structure responses due to the three components of the SSI analysis input motion are combined in the time domain.
- Time histories are obtained from SSI analysis cases that are critical for the designed subsystem and include those obtained from BE soil case.
- Time shifting is applied to the time histories to address uncertainties related to the modeling of natural frequencies of supporting structure.

3.7.2.5.3 Relative Displacement

Relative displacement between different support points of subsystems with multiple or distributed supports are evaluated using the support displacement time histories.

The time history of the relative displacements corresponding to each SSI analysis is obtained by algebraic calculation of the difference in displacement time histories at the support locations. Directional combination of the support displacement time histories is carried out on a time-step-by-time-step basis or using the SRSS method as described in Subsection 3.7.2.6. Maximum design relative displacements are calculated as the envelope of the maximum relative displacements obtained for each SSI analysis case.

3.7.2.6 Three Components of Design Ground Motion

Earthquake motion is three dimensional and seismic design takes into account the effects of the three orthogonal components (two horizontal and one vertical) of the prescribed design earthquake.

The SSI analyses are performed separately for each of the three directional components of input ground motion using five sets of time histories as discussed in Subsection 3.7.1.1.2. For each set of time histories used as analysis input, the seismic response parameters obtained from the analysis of each of the three ground motion components are combined to get the total co-directional response with either of the three methods permitted under Section 4.2.2 of ASCE/SEI 4-16, and RG 1.92, “Combining Modal Responses and Spatial Components in Seismic Response Analysis.”

1. The time histories of responses due to the three earthquake components are combined algebraically on the time-step-by-time-step approach.

2. The maximum co-directional responses can be combined using the 100-40-40 method.

3. The maximum responses due to the three earthquake components can be combined using SRSS method.

The absolute sum method used in time domain is implemented (e.g., for calculations of seismic demands for foundation bearing pressure and stability evaluations) as an alternative to performing the algebraic sum method for all possible combinations of the input motion directions.

3.7.2.7 Combination of Modal Responses

Modal combination is not utilized for the analysis of the Seismic Category I structures. These structures are evaluated using ACS SASSI FE models. ACS SASSI utilizes the frequency domain analysis method in which the equations of motion are solved for the selected range of frequencies defined in Subsection 3.7.2.1.1.

3.7.2.8 Interaction of Non-Seismic Category I Structures with Seismic Category I SSCs

To meet the interaction guidance of Section II.8 of SRP 3.7.2, evaluations are performed of the lateral load resisting system of the RWB, CB, TB, Service Building and Reactor Auxiliary Structures following the approach in Section 6.2 of NEDO-33914-A. These evaluations are based on seismic responses of RWB, CB, TB, Service Building and Reactor Auxiliary Structures obtained from the SSI analyses that incorporate the dynamic response of the RB and surrounding Power Block structures. The FE models of the RWB, CB, TB, Service Building and Reactor Auxiliary Structures included in the SSI combined model are refined sufficiently to provide accurate stress demands on the major lateral load resisting structural members and accurate seismic displacements in the direction of the adjacent RB.

The seismic interaction evaluations consider limited permanent deformations (Limit State LS-C) structural response to calculate SSE demands for the main lateral load resisting structural members following the guidance of Section 6.2 of NEDO-33914-A.

The gaps between the RB and adjacent structures are evaluated per guidance in Section 6.2 of NEDO-33914-A to ensure no physical interaction between the RB structure and surrounding structures. The gaps are evaluated along the entire height of the adjacent structures considering construction tolerances, inelastic deformations, and possible differential settlements.

3.7.2.9 Effects of Parameter Variations on Responses

Uncertainties in structural properties, damping values, subgrade properties, and variations of SSI parameters are accounted for in the analysis and design of BWRX-300 Seismic Category I structures in accordance with Section II.4 of SRP 3.7.2, Section 5.1 of ASCE/SEI 4-16, and following the guidance of Section 5.3 of NEDO-33914-A.

The NEDO-33914-A specified sensitivity analysis cases are modified to adequately address the SSI parameter uncertainties related to the specific layout of the CRN seismic SSI analysis model described in Subsection 3.7.2.3. The following subsections present the modified approach for evaluating the effects of parameter variations on the integrated RB responses at the CRN Site.

As stated in Subsection 3.7.2.4, the sensitivity analyses are performed using the SSI model with the adjacent Power Block structures. Evaluations of effects of parameter variations on floor responses are based on comparisons of in-structure responses and stress demands at key locations selected as discussed in Subsection 3.7.2.2, obtained from the sensitivity analyses as described below.

For the results of the sensitivity analyses performed for the BWRX-300 at the CRN Site, refer to Appendix 3C.

3.7.2.9.1 Effects of Variation of Structural Stiffness and Damping Properties

Effective structural BE stiffness and lower OBE damping properties are assigned to the integrated RB FE model as discussed in Subsection 3.7.2.3. Effective stiffness assigned to steel-plate composite members considers the level of stress due to the most critical seismic load combinations following the recommendations in Section 5.3.5 of NEDO-33914-A.

If the estimated stresses in the steel-plate composite structural members in the design basis BE case meet the applicable stress level criteria for Response Level 2 per ASCE/SEI 43-19, a sensitivity SSI analysis is performed to address the effects of structural stiffness variations on models where the steel-plate composite structural members are assigned LB stiffness and higher SSE damping properties. In accordance with Section 5.3.5 of NEDO-33914-A, the sensitivity analysis is performed for BE subgrade profile.

The effects of structural stiffness variations are assessed by comparing the key in-structure responses selected as described in Subsection 3.7.2.2 and stress demands obtained from the sensitivity analysis of the models with reduced stiffness properties with results of the design basis analysis performed on the model with effective stiffness properties. If the comparisons show significant exceedances (> 10%) in the RB seismic response due to the structural stiffness variations, the results of the sensitivity analysis are included in the RB seismic design basis.

3.7.2.9.2 Excavation Support, Backfill and Friction Effects

Excavation support and backfill effects are addressed following the guidelines of Section 5.3.8 of NEDO-33914-A with a few modifications given that the concrete fill around the RB is included in the RB SSI model as discussed in Subsection 3.7.2.3. Refer to Subsection 3.7.2.9.7 for a discussion on how uncertainties related to the concrete fill are addressed.

As stated in Subsection 3.7.2.3, the CRN excavation plan considers the use of temporary excavation support for the soil around the RB excavation above top of rock. The uncertainty related to the excavation support may be investigated by performing a sensitivity SSI analysis using the RB model with adjacent Power Block structures supplemented by the explicit modeling of the excavation support and BE properties of surrounding subgrade materials. Shell and beam elements or solid elements may be used to represent the BE dynamic properties of the excavation support.

The technique used for the RB shaft construction and corrosion allowance can also affect the friction at the interfaces between the RB exterior wall and the surrounding concrete fill material. To address the uncertainties related to the modeling of friction at the RB shaft interfaces, a sensitivity SSI analysis is performed by considering the no-friction conditions assuming no friction resistance between the RB exterior wall and the surrounding concrete fill following the guidance in Section 5.3.8 of NEDO-33914-A.

Results of these sensitivity analyses for the key in-structure responses and stress demands selected as described in Subsection 3.7.2.2 are compared with the corresponding results of the design basis SSI analyses of the FE model that excludes the excavation support and assumes fully bonded conditions at the RB-subgrade interfaces. If the comparisons show significant

exceedances (> 10%) in the RB seismic response due to the interaction with the excavation support or no-friction conditions, the results of these sensitivity analyses are included in the RB seismic design basis.

3.7.2.9.3 Groundwater Variation Effects

The potential effects of groundwater level variability on the seismic design of the RB are addressed following the guidelines of Section 5.3.10 of NEDO-33914-A.

The seismic design of the RB is based on the analysis of models that reflect fully saturated conditions for soil materials located below the nominal groundwater elevation. The potential effects of groundwater level variability on the seismic design are addressed by comparing the seismic responses obtained from the SSI analysis with fully saturated conditions with the responses obtained from the SSI analysis of a dry soil profile. The dry soil profile may use BE soil dynamic properties representative of the conditions of the LB groundwater level at the CRN site. Alternatively, the groundwater may be conservatively considered to be located below the RB foundation bottom elevation.

If the comparisons show that the effects of groundwater variation exceed 10%, the design basis seismic demands are developed based on the fully saturated soil profile.

3.7.2.9.4 Soil Separation Effects

The SSI analysis of the RB addresses the uncertainties related to the inability of linear models used for the seismic analysis to explicitly represent the separation between the soil and the structure, following the guidance of Section 5.1.9(b) of ASCE/SEI 4-16 and Section 5.3.9 of NEDO-33914-A.

A sensitivity SSI analysis is performed on a model where portions of the concrete fill that may experience separation from the surrounding subgrade soil are assumed to remain unbonded for the total duration of the earthquake. The extent of soil separation is assessed by comparing the maximum lateral earth pressure calculated from the seismic SSSI analysis of BE subgrade profile with a LB estimate of static earth pressures. The static lateral pressures calculated from static design SSI analysis with 1-g loading (see Subsection 3.8.4.1.4), are reduced by 10% to account for uncertainties in calculation of soil unit weights and surcharge loads. The regions where the static lateral pressure is lower than the seismic lateral pressure are considered separated in the model used for the sensitivity analysis. Alternatively, the separation may be conservatively considered for the full depth of soil, down to the top of un-weathered rock.

The key in-structure responses selected as described in Subsection 3.7.2.2, and stress demands calculated from this sensitivity analysis are compared to the corresponding results of the SSI analysis of the model with BE properties representing fully bonded conditions. If the comparisons indicate that the seismic in-structure responses and stress demands from the model with soil separation exceed those obtained from the SSI analysis of fully bonded models by more than 10%, the results of the sensitivity analysis are included in the RB seismic design basis.

3.7.2.9.5 Effects of Non-Vertically Propagating Seismic Waves

The potential for non-vertically propagating seismic waves at the CRN Site is assessed following the guidelines in Section 5.3.3 of NEDO-33914-A, based on the geological and seismological conditions of the site.

As discussed in Subsection 2.5.2.6, a Two-Dimensional (2D) sensitivity analysis is performed to investigate the effect of the approximately 33-degree dip of rock layers on site response results. The response spectra results from the 2D analysis indicate that the response spectra from the 1D analysis presented in Subsection 3.7.1 adequately envelop the effects of non-vertically propagating seismic waves on the input ground motion.

3.7.2.9.6 Non-Linear Sensitivity Evaluation

Results of the foundation interface analysis presented in Subsection 2.5.4.13, indicate that the RB at the CRN Site is mainly embedded in rock and exhibits nearly linear elastic behavior during SSE level event. The ground motion at the CRN site is characterized by high energy content in high frequencies resulting in subgrade strains with a low amplitude. Therefore, the effects of the non-linearity of subgrade materials on the seismic response and design of RB are insignificant.

3.7.2.9.7 Concrete Fill Strength

The inclusion of the concrete fill in the RB 3D FE model introduces the additional uncertainty over the strength of the concrete fill which is not designed to maintain its structural integrity throughout the operational life of the plant. To address this uncertainty, an additional sensitivity evaluation is performed using a reduced value of the design concrete fill strength. Responses calculated from this sensitivity analysis are compared to results obtained from the SSI analysis of the RB model with adjacent Power Block structures with design concrete fill strength. If the comparisons show significant exceedances (> 10%) in the RB seismic response due to the change in concrete fill strength, the results of this sensitivity analysis are included in the RB seismic design basis.

3.7.2.10 Use of Equivalent Vertical Static Factors

Constant vertical static factors are not used in the design of the Seismic Category I structures. Vertical seismic loads are directly obtained from the results of SSI analyses performed using the one-step design analysis approach discussed in Subsection 3.7.2.1.

3.7.2.11 Methods Used to Account for Torsional Effects

Considerations are given in the modeling of the integrated RB structure to represent the actual locations of the center of masses and centers of rigidity of structural elements to account for torsional effects as discussed in Subsection 3.7.2.3.1.

In accordance with the requirements of Section 3.1 of ASCE/SEI 4, the seismic design of the RB structure also considers accidental torsion to account for:

- Non-vertically propagating seismic waves
- Rotational components of ground motion

- Distributions of structural mass and stiffness that differ from those represented in the 3D FE model used for the seismic response analysis

Following the guidance of Section II.11 of SRP 3.7.2, the accidental torsional moment demands are calculated at each floor level as the product of the story shear and 5% of the floor plan dimension perpendicular to the story shear direction. Alternatively, the horizontal shear force demands on walls may conservatively be increased by 5% to account for the accidental torsion.

3.7.2.12 Comparison of Responses

Because only the time history method is used for the dynamic analysis of Seismic Category I structures, a comparison of responses with the response spectrum method is not applicable.

3.7.2.13 Analysis Procedure for Damping

Refer to Subsection 3.7.1.2 for damping values used in the SSI analysis of Seismic Category I SSCs.

3.7.2.14 Determination of Seismic Overturning Moments and Sliding Forces, Structure to Soil Pressures and Frictional Forces for Seismic Category I Structures

Consistent with the guidance of Section II.14 of SRP 3.7.2, contact spring elements installed in the one-step SSI models at interfaces between the structure and the subgrade are used for calculation of dynamic bearing pressure demands, seismic driving forces and overturning moments on the Seismic Category I common mat foundation. Uncertainties related to friction at the RB shaft interfaces are addressed as described in Subsection 3.7.2.9.2.

As described in Subsection 3.7.2.6, time histories of the horizontal and vertical seismic forces in the three directions are calculated as the algebraic sum of the forces in the three directions at each step for all contact spring elements. Overturning moments about the two horizontal axes are calculated as the algebraic sum of the moments resulting from each spring force with respect to the foundation bottom centerline.

The seismic inertia forces and overturning moments for the foundation stability evaluations and seismic bearing pressure calculations may be obtained from SSI models with higher SSE structural damping values.

The RB seismic bearing pressure demands are also calculated in the time domain. Maximum bearing pressure values are calculated for the total duration of earthquake for each of the five sets of ATHs used as input for the SSI analysis discussed in Subsection 3.7.1.1.2. The dynamic bearing pressure demand under the RB foundation is defined as the average of the results obtained from the five sets of ATHs.

3.7.3 Seismic Subsystem Analysis

This section focuses on the seismic qualification by analysis of the BWRX-300 Seismic Category I subsystems which consists of:

- Distribution systems, including piping and supports, cable trays and supports, heating, ventilation and air conditioning ductwork and supports, conduits and supports,
- Equipment supports,
- Intervening structural elements between distribution systems and equipment supports and the RB structure, and
- RPV and internals.

Input motions for the qualification of these subsystems are usually in the form of floor response spectra or ATHs obtained from the integrated RB seismic SSI analysis discussed in Subsection 3.7.2. Input motions in terms of acceleration time histories are generally used. For other methods used in the seismic and dynamic qualifications of subsystems, refer to Section 3.10.

3.7.3.1 Seismic Analysis Methods

Seismic analysis of subsystems is performed using one of the following methods in accordance with SRP 3.7.2, Section II.1:

- Time history analysis
- Response spectrum analysis
- Static coefficient

3.7.3.1.1 Time History Analysis

Assuming velocity proportional damping, the dynamic equilibrium equations for a lumped mass, distributed stiffness system are expressed in matrix form as:

$$[M] \{\ddot{u}(t)\} + [C] \{\acute{u}(t)\} + [K] \{u(t)\} = \{P(t)\}$$

where:

$\{u(t)\}$ = time dependent displacement of nonsupport points relative to the supports.

$\{\acute{u}(t)\}$ = time dependent velocity of nonsupport points relative to the supports.

$\{\ddot{u}(t)\}$ = time dependent acceleration of nonsupport points relative to the supports.

$[M]$ = mass matrix.

$[C]$ = damping matrix.

$[K]$ = stiffness matrix.

{P(t)} = time dependent applied force column vector.

The above equation is solved by modal superposition or direct integration in the time domain.

Modal superposition involves two steps. First, the characteristic equation corresponding to undamped, free vibration of the model is solved to obtain the eigenvalues, eigenvectors, and generalized masses. The system coupled equations are then decoupled via the eigenvector transformation matrix which is simply the matrix of eigenvectors written as columns. The equations are decoupled in the generalized coordinate system because of the orthogonality of the matrix of eigenvectors with respect to the “weighted” mass and stiffness matrices. The decoupled modal equations are then solved independently to obtain the generalize coordinates. The physical solution is then given by the eigen transformation once the generalized coordinates are known.

The direct integration method involves the numerical integration of the simultaneous differential equations of equilibrium in their original form, without transformation to the generalized coordinates. For systems subjected to short duration, high frequency excitation, the direct integration method requires less computation and is recommended over the modal superposition method.

For the time domain solution, the numerical integration time step is sufficiently small to accurately define the dynamic excitation and to render stability and convergence of the solution up to the highest frequency (or shortest period) of significance. This condition is satisfied if Δt is selected to limit the amplitude decay per cycle of free vibration of the highest significant mode to less than 20%. This corresponds to approximately 3.5% numerical damping for that highest significant mode. The integration time step for both the direct numerical integration of the system coupled equations of motion and the numerical integration of the n decoupled equations (modal superposition) satisfies the following requirement:

$$\Delta t \leq T_m/10$$

where Δt is the numerical integration time step magnitude and T_m is the period of the highest significant mode considered in the analysis or the reciprocal of the cutoff frequency in Hz as defined in Subsection 3.7.3.4.

3.7.3.1.2 Response Spectrum Analysis

This method is used if only peak dynamic responses are required.

The response spectrum method is a modal superposition analysis in which only the peak values of the solution of the decoupled modal equations are obtained. The method is based on writing the solution of each decoupled modal equation in terms of the convolution integral. The major advantage of this form of solution is that for a given input motion the only variables under the integral are the damping factor and the frequency. Thus, for a specified damping factor, it is possible to construct a curve which gives the maximum value of the integral as a function of

frequency. This curve is called a response spectrum for the particular input motion and the specified damping factor. The integral has units of velocity, consequently the maximum of the integral is called the spectral velocity.

For a subsystem analysis of a secondary system the input floor response spectra, obtained from a time history analysis of the primary system, is broadened ±15% to account for modeling uncertainties in both the primary and secondary systems in accordance with RG 1.122 and Section 6.2.3 of ASCE/SEI 4.

Using the calculated natural frequencies of vibration of the system, the maximum values of the modal responses are determined directly from the appropriate response spectrum. The modal maxima are then combined as discussed in Subsection 3.7.3.7.

3.7.3.1.3 Static Coefficient

The static coefficient method may be applied to certain equipment in lieu of the required dynamic analysis. Response loads are determined statically by multiplying the equipment mass by a static coefficient equal to 1.5 times the maximum spectral acceleration in accordance with SRP 3.7.2, Section II.1.B. This coefficient is intended to account for the effect of both multi-frequency excitation and multi-mode response. This method is applicable only to equipment corresponding to a simple column, beam, or frame type structure supported at a single point. Justification is required for applying this method or coefficient to equipment having configurations other than simple frame or beam type structures.

A factor of less than 1.5 may also be used if adequate justification is provided in accordance with SRP 3.7.2, Section II.1.B. For example, if the equipment is simple enough such that it behaves essentially as a single degree-of-freedom model and the fundamental frequency is greater than the seismic excitation frequency, the factor 1.0 can be used instead of 1.5.

If the fundamental frequency of the equipment is greater than the cutoff frequency but less than the Zero Period Acceleration (ZPA) frequency, the static coefficient can be taken as 1.5 times the peak spectral acceleration which occurs between the cutoff frequency and the ZPA frequency in the equipment input response spectra.

3.7.3.1.4 Seismic Analysis of Piping Systems

The time history and the response spectrum methods are utilized in the piping analysis as required. The procedure for multi-support excitation described in Subsection 3.7.3.9 is followed with both methods. When the multi-support response spectrum method is used to calculate the dynamic response of the piping system, all multi-support response spectra components are simultaneously applied to each piping model for each load case.

Secondary stresses due to anchor displacements may be calculated based on total anchor displacements or on a mode-by-mode basis. As a conservative approach, the maximum displacement of each support point can be computed by either time history analysis or response spectrum analysis for the supporting RB Structures. The computed individual maximum support

displacements are then imposed on the supported piping and equipment systems in the most limiting, or severe, directional combination for the piping and equipment design verification consideration.

The dynamic loads on pipe mounted pumps and valves are determined by dynamic analysis of the piping system including the pumps and valves in the analytical model. If a pump or valve has a fundamental frequency greater than the cutoff frequency described in Subsection 3.7.3.4, it may be modeled as a rigid body. The pump or valve fundamental frequency is calculated for the equipment alone when it is rigidly supported at the nozzle where it interfaces with the piping system.

3.7.3.1.5 Seismic Analysis of Equipment

The time history and response spectrum methods are also utilized in the equipment analysis as required. When the equipment is supported at two or more points located at different elevations in the building, the response spectrum for the most severe single point of attachment is chosen as the design spectra. Alternatively, the multi-support excitation procedure described in Subsection 3.7.3.9 is used.

The relative displacement between supports is determined from the dynamic analysis of the structure. The relative support-point displacements are used for static analysis to determine the additional stresses due to support displacements. As discussed in Subsection 3.7.3.1.3, the static coefficient method may be used in lieu of the required dynamic analysis for rigid equipment and frame type structures supported at a single point.

Seismic qualification of equipment by testing is discussed in Section 3.10.

3.7.3.1.6 Seismic Analysis of the Reactor Pressure Vessel and Internals

To capture the interaction of the integrated RB structures with the RPV and its internals components, such as fuel, guide tubes, and Control Rod Drive (CRD) system housing, a LMS model representing the RPV dynamic properties is included in the integrated RB model as discussed in Sections 3.7.2.3.2 and 3.7.3.3.3.

The dynamic responses required as input for the design verification of RPV and internals components are generated directly in the dynamic analysis of the RB. Seismic acceleration time histories for the design of the RPV and internals are applied to the RPV and internals model simultaneously in the three orthogonal directions. Alternatively, two analyses can be performed to calculate the horizontal and vertical responses of the RPV separately.

The evaluation of RPV internals components in the horizontal direction is performed using a two-step analysis approach, where seismic accelerations at RPV support locations are applied to more detailed FE models of the RPV and internals. The first step of the two-step analysis consists of obtaining ATHs developed as described in Subsection 3.7.2.5 at the RPV/RB interface locations from the RB SSI analyses discussed in Subsection 3.7.2. The second step is a multi-support excitation time history analysis of the RPV, and internals subjected to the ATHs generated in the first step. The procedure for multi-support excitation time history analysis, as

described in Subsection 3.7.3.9, is followed in the second step analysis of the RPV and internals. In accordance with the requirements of Section 6.3.2 of ASCE/SEI 4, time step of the input time histories is varied to address uncertainties related to the modeling of natural frequencies of the supporting structure and the SSI analysis methodology as stated in Subsection 3.7.2.5.2.

3.7.3.2 Determination of Number of Earthquake Cycles

The determination of the number of earthquake cycles for subsystem analysis is in accordance with Section II.2 of SRP 3.7.3, “Seismic Subsystem Analysis Review Responsibilities.”

3.7.3.3 Procedures Used for Analytical Modeling

The mathematical models for Seismic Category I components are developed to realistically reflect the dynamic characteristics of the components.

To do so, each component is discretized into a series of interconnected beam elements or FEs. The node points are generally selected to coincide with the locations of large masses, such as at structure floors or at heavy equipment supports, and at points corresponding to any significant change in physical geometry.

The number of mass node points in the model is sufficient if additional node points (independent of number) do not result in more than 10% increase in the responses in the frequency range below the cutoff frequency specified in Subsection 3.7.3.4.

The node point spacing is selected such that the maximum length (L) of the FE between any two node points, in the direction of the stress wave propagation, satisfies the condition:

$$L \leq \frac{\lambda}{4} = \frac{\mathrm{v}}{4f} = \frac{\mathrm{vT}}{4}$$

where λ and v are the wavelength and wave velocity, respectively. The frequency f, or period T, correspond to the cutoff frequency of Subsection 3.7.3.4.

3.7.3.3.1 Modeling of Piping Systems

The continuous Seismic Category I piping systems are modeled as an assemblage of pipe elements (e.g., straight sections, elbows, and bends) supported by hangers and anchors, and restrained by pipe guides, struts, and snubbers. Pipe and fluid masses are lumped at the nodes and connected by the weightless elastic beam elements which reflect the physical properties of the corresponding piping segment. The mass node points are selected to coincide with the locations of large masses, such as valves, pumps, and motors, and with locations of significant geometry change. Concentrated weights on the piping system, such as the valves, pumps, and motors, are modeled as lumped mass rigid systems if their fundamental frequencies are greater than the cutoff frequency in Subsection 3.7.3.4. The torsional effects of valve operators and other equipment with off-set center of gravity with respect to the piping centerline are included in the

analytical model. The pipe length between mass points is no greater than the length with a fundamental frequency equal to the cutoff frequency stipulated in Subsection 3.7.3.4 when calculated as a simply supported beam with uniformly distributed mass.

All pipe guides and snubbers are modeled to produce representative stiffness to reduce modeling uncertainties. Snubbers are modeled with an equivalent stiffness based on dynamic tests or on data provided from the vendor. The stiffness of the supporting structures is included in the analysis unless the supporting structure is shown to be rigid.

3.7.3.3.2 Modeling of Equipment

For dynamic analysis, Seismic Category I equipment is represented by lumped mass systems which consist of discrete masses connected by weightless beam elements and/or by any other appropriate FE representation. The criteria used to lump the masses are:

- The number of modes of dynamic system is controlled by the number of masses used. Therefore, the number of masses is chosen so that all significant modes are included. The modes are considered as significant if the corresponding natural frequencies are less than the cutoff frequency specified in Subsection 3.7.3.4.
- Mass is lumped at any point where a significant concentrated weight is located.
- For equipment with a free-end overhang span whose flexibility is significant compared to the center span, a mass is lumped at the overhang span.
- When a mass is lumped between two supports, it is located at a point where the maximum displacement is expected to occur. This tends to conservatively lower the natural frequencies of the equipment. Similarly, in the case of live loads and a variable support stiffness, the location of the load and the magnitude of support stiffness are chosen to yield the lowest frequency content for the system.

3.7.3.3.3 Modeling of Reactor Pressure Vessel and Internals

Because of the significant dynamic interaction between the RB and RPV and internals, the latter are integrated into the RB model as discussed in Subsection 3.7.2.3 and Appendix 3B.

The mathematical model of the RPV and internals consists of a LMS model connected by linear elastic members and 3D FE models. Using the elastic properties of the structural components, the stiffness properties of the model are determined. This includes the effects of both bending and shear.

To facilitate hydrodynamic mass calculations, mass points (e.g., representing the fuel, shroud, vessel) are selected at the same elevation. The various lengths of CRD housings are grouped into two representative lengths. These lengths represent the longest and shortest housings to adequately represent the full range of frequency response of the housings. To reduce the complexity of the dynamic model, the light components (such as incore guide tubes and housing, sparger, and their supply headers) are excluded from the RPV mathematical model. However, the dynamic response of selected components is determined from a subsystem analysis after the system response is found.

Dynamic effects of water enclosed by the RPV are accounted for by introduction of a hydrodynamic mass matrix, which serves to link the acceleration terms of the equations of motion of points at the same elevation in concentric cylinders with a fluid entrapped in the annulus. Although the dynamic coupling between the vertical hydrodynamic masses is not considered, the vertical hydrodynamic masses themselves are properly accounted for. Dynamic loads due to vertical motion are added to, or subtracted from, the static weight of component, whichever is more conservative.

The shroud support plate is modeled as a rigid link in the translational direction because it is loaded in its own plane during a horizontal dynamic event. The shroud support legs, and the local flexibilities of the vessel and shroud contribute to the rotational flexibilities and are modeled as an equivalent torsional spring.

Due to the small clearances in the horizontal directions, the fuel assembly is adequately modeled as a linear system for subsystem and system analysis. In the vertical direction, the fuel assembly has the potential to lift off from its seat and a non-linear representation is required if the vertical applied and reaction forces are sufficient to cause fuel lift. Furthermore, the interface between the fuel channel and lower plate tie plate is not rigid and a non-linear model to account for slippage may be appropriate.

The weight of asymmetric secondary components, such as attached equipment, is uniformly redistributed around the node point circle. Asymmetric equipment is modeled using FE or LMS methods.

3.7.3.4 Basis for Selection of Frequencies

The cutoff frequency selected in the time history and response spectrum analyses ensures that all significant modes are included in the superposition. Higher modes which cumulatively contribute less than 10% of the total system response are not considered in the superposition of the individual modal values.

The cutoff frequency for seismic and other dynamic loads follows Subsection 3.7.2.1.1. For seismic load, modes up to 100 Hz are included. For other dynamic analysis, the cutoff frequency is 100 Hz, as long as no more than 5% of the total strain energy of the system remains beyond this cutoff frequency.

Where practical, to avoid adverse resonance effects, equipment and components are designed/selected such that their fundamental frequencies are approximately less than half or more than twice the dominant frequencies of the support structure following the regularity guidance of Section II.4 of SRP 3.7.3. Moreover, the equipment is analyzed or tested or both to demonstrate that it is adequately designed for the applicable loads considering both its fundamental frequency and the forcing frequency of the applicable support structure.

3.7.3.5 Analysis Procedure for Damping

3.7.3.5.1 RPV and Internals Damping

Damping values for seismic analysis of the RPV and internals using the modal superposition method are presented in Table 3.7-6. These damping values are in accordance with ASCE/SEI 43-19 and are consistent with RG 1.61, with the CRD damping values exceeding the guidance for a welded steel construction. Fuel damping is in accordance with NEDE-21175-3-P-A which states that damping of fuel elements is in accordance with RG 1.61.

The Rayleigh damping is used for FE analysis of the RPV and internals when using the direct integration method.

3.7.3.5.2 Damping for Piping, Equipment and Equipment Support

Damping coefficients used in the seismic analysis of Seismic Category I piping, equipment, equipment supports and intermediate structures between subsystems are presented in Table 3.7-7. These damping values are consistent with RG 1.61.

3.7.3.6 Three Components of Design Ground Motion

Applicable methods for spatial combination of responses due to each of the three input motion components are described in Subsection 3.7.2.6.

3.7.3.7 Combination of Modal Responses

Modal combination procedures are in accordance with Section II.7 of SRP 3.7.2 and RG 1.92.

3.7.3.8 Interaction of Non-Seismic Category I Subsystems with Seismic Category I SSCs

The methodology used for evaluation and design of Non-Seismic Category I subsystems interacting with Seismic Category I SSCs is consistent with Section II.8 of SRP 3.7.3.

3.7.3.9 Multiple-Supported Equipment and Components with Distinct Inputs

The BWRX-300 approach for analyzing equipment and components supported at several points by either a single structure or two separate structures conforms with the guidance of Section II.9 of SRP 3.7.3.

The time history direct integration, time history modal superposition and response spectrum modal superposition methods discussed in Subsection 3.7.3.1 can be used in multi-support excitation analysis. However, the mode superposition procedure described in Subsection 3.7.3.1 for an applied load vector is replaced with the corresponding mode superposition procedure for multi-support excitation analysis.

When using the time history or response spectrum methods, the following methods are acceptable:

1. The uniform support motion method, where uniform time histories corresponding to the envelopes of all individual ISRS at the various support locations are applied at each attachment point simultaneously.

2. The independent support motion method, where time histories corresponding to the envelopes of the ISRS for each attachment point in each of the three directions are applied at each corresponding attachment point simultaneously.

The above time history methods of analysis are performed such that inertial (primary) and static stresses (secondary) due to differential displacements are separated. The inertial forces are used for primary stress calculations. For closely spaced modes of the supporting structure, the response is calculated as discussed in Subsection 3.7.3.7. The total secondary stress for triaxial excitation is computed as the SRSS of the resultant secondary stresses for each excitation direction. The American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code (BPVC), Section III, “Rules for Construction of Nuclear Facility Components,” (Reference 3.7-10) requires that the secondary stresses must be combined with the primary stress.

Using the response spectrum method, the support points response spectra are generated from support point acceleration time histories with ±15% peak broadening to account for the RB support structure modeling uncertainties in accordance with RG 1.122 and Section 6.2.3 of ASCE/SEI 4-16. For uncorrelated dynamic inputs, the use of the SRSS method to combine modal responses is appropriate because the modal excitation maximum responses do not occur simultaneously and therefore are statically uncorrelated. For situation of high modal density, i.e., when the significant modes are “closely spaced”, the modal responses could be highly correlated and the SRSS superposition may yield unconservative responses. In this case, the modal responses are initially combined algebraically, then combined with the uncorrelated responses using the SRSS method.

3.7.3.10 Use of Equivalent Vertical Static Factors

Equivalent vertical static factors are used when the requirements for the static coefficient method in Subsection 3.7.3.1.3 are satisfied.

3.7.3.11 Torsional Effects of Eccentric Masses

Torsional effects of eccentric masses are considered in the modeling of subsystems as discussed in Subsection 3.7.3.3.

3.7.3.12 Seismic Category I Buried Piping, Conduits and Tunnels

The BWRX-300 design does not include Seismic Category I buried pipes, conduits, or tunnels.

3.7.3.13 Methods for Seismic Analysis of Seismic Category I Concrete Dams

The design does not include nor require the presence of a dam.

3.7.3.14 Methods for Seismic Analysis of Above-Ground Tanks

The BWRX-300 design does not include Seismic Category I above-ground tanks.

3.7.3.15 Effect of Differential Building Movements

In most cases, subsystems are anchored and restrained to floors and walls of buildings that may have differential movements during a seismic event.

Differential endpoint or restraint deflections cause forces and moments to be induced in the system. As discussed in Subsection 3.7.3.9, the stress thus produced is a secondary stress. It is justifiable to place this stress, which results from restraint of free-end displacement of the system, in the secondary stress category because the stresses are self-limiting and, when the stresses exceed yield strength, minor distortions or deformations within the system satisfy the condition which caused the stress to occur.

Refer to Subsection 3.7.2.8 for the methodology used to obtain differential displacements used in the evaluation of subsystems.

3.7.4 Seismic Instrumentation

As required in 10 CFR 50, Appendix S, instrumentation is provided so that the seismic response of safety class SSCs can be evaluated promptly after an earthquake.

The BWRX-300 seismic instrumentation system meets the relevant requirements of GDC 2, 10 CFR 50.65, 10 CFR 50, Appendix S, and 10 CFR 50.55a “Codes and Standards and is consistent with SRP 3.7.4, “Seismic Instrumentation,” and RG 1.12, “Nuclear Power Plant Instrumentation for Earthquakes.” The instrumentation used for the measurements is capable of recording the effects produced by the most severe earthquakes that have been historically reported for the unique site considered and surrounding area, with sufficient margin for the limited accuracy, quantity and period of time in which historical data has been accumulated.

Provisions for inservice testing, remote alarm, recording capabilities, dynamic range and sampling rate with a low and adjustable actuating level or trigger, and data processing are in accordance with RG 1.12 and RG 1.166, “Pre-Earthquake Planning, Shutdown, and Restart of a Nuclear Power Plant Following an Earthquake.”

3.7.4.1 Comparison with Regulatory Guide 1.12

The seismic instrumentation program described in the following subsections is consistent with RG 1.12.

3.7.4.2 Location and Description of Instrumentation

3.7.4.2.1 Free-Field Instrumentation

The location of the free-field instrumentation follows the guidance of Section C.1.2 of RG 1.12, and include:

- At least two triaxial accelerometers installed outside of the structure-ground interaction influence of the Power Block, but as close as practicable to the RB following the guidance of Section C.1.3.1 of RG 1.12.
- At least one free-field downhole accelerometer installed at the depth of bottom of the RB foundation, below the free-field accelerometer at finished grade level, because the deeply embedded RB is founded at a depth more than 12 m (40 ft) below finished grade elevation.

3.7.4.2.2 Structure and Component Instrumentation

In accordance with the requirements of Section C.1.2 of RG 1.12, triaxial accelerometers are installed at several locations inside the RB:

1. At least one accelerometer at the top of the RB base slab
2. One accelerometer on the containment internal structure close to the reactor vessel
3. One accelerometer in the RB close to the top of the containment internal structure
4. One accelerometer close to the top of the containment structure
5. One accelerometer at the top of the operating floor elevation

Triaxial accelerometers are installed at three locations outside the RB deemed important in accordance with Section C.1.2 of RG 1.12.

The specific locations for instrumentation are determined to obtain the most pertinent information consistent with the selected key locations in the RB model to enable easy comparison between the measured and calculated in-structure responses in accordance with Section C.1.3.2 of RG 1.12.

Most of the instrumentation stations are configured to be accessible for maintenance during full-power operation in compliance with the guidance of Section C.4.3 of RG 1.12. For sensors installed in inaccessible areas, provisions for data recording, external remote alarm indicating actuation and remote inservice inspections are provided.

3.7.4.2.3 Recording and Playback Equipment

Recording and playback units are provided for multiple channel recording and playback of the triaxial accelerometer signals. Characteristics of the recording and playback equipment follow the guidelines in Section C.4 of RG 1.12.

3.7.4.3 Control Room Operator Notification

Activation of the seismic trigger causes an audible and visual annunciation in the two control rooms to alert the plant operator that a felt earthquake has occurred in accordance with Section C.7 of RG 1.12.

For other control room design requirements, refer to Section 6.4.

3.7.4.4 Comparison of Measured and Predicted Responses and Conformance with RG 1.166

The BWRX-300 pre-earthquake planning, and post-earthquake actions are in accordance with RG 1.166, including clarifications, and American National Standards Institute (ANSI)/American Nuclear Society (ANS)-2.23, “Nuclear Power Plant Response to an Earthquake,” (Reference 3.7-11) endorsed by RG 1.166.

Following a seismic event, operator actions and operator walkdown inspections are performed to assess the severity of the earthquake following the provisions of Section 6 of ANSI/ANS-2.23. The data from the seismic instrumentation, coupled with information obtained from a plant walkdown, is used to make the initial determination of whether the plant should be shut down, if it has not already been shut down by operational perturbations resulting from the seismic event. The plant is shut down if the walkdown inspections discover damage to equipment that would affect the safe operation of the plant, or if the OBE exceedance criteria determined in accordance with Section 6.4.1 of ANSI/ANS-2.23, are met.

Following plant shutdown, post-shutdown inspections and tests are performed in accordance with Sections 7.1, 7.2, 8.1 and 8.2 of ANSI/ANS-2.23 to determine the physical condition of the plant and its readiness to resume operation. Long term evaluations are performed following the requirements and guidelines of Section 9 of ANSI/ANS-2.23. After plant is restarted (or prior to restart if the earthquake caused significant damage to the plant), long-term evaluations are carried out for engineering assessments of plant structures and equipment using the actual event records to assure their long-term reliability. Results of post-shutdown inspections and tests are documented and are available for inspection prior to restart.

3.7.4.5 Design, Installation, and Inservice Surveillance

The seismic instrumentation is expected to operate during all modes of plant operation including periods of plant shutdown. The design, selection, and location of the BWRX-300 seismic instrumentation includes consideration for long service life, ease and low frequency of maintenance and calibration.

The instrumentation is designed and installed following the guidance of Sections C.4 and C.5 of RG 1.12.

Prior to installation, the operational reliability of the seismic monitoring instrumentation is demonstrated in accordance with Section C.4.7 of RG. 1.12.

Maintenance, testing and administrative procedures for seismic instrumentation defined in accordance with Section C.9 of RG 1.12 are documented before the first facility start-up, and updated as necessary following any modification to the system. Following the guidance of Section C.3 of RG 1.12, the seismic instrumentation system components are maintained and tested to ensure that a maximum number of instruments are kept in service during plant operation and shutdown. The maintenance program addresses technical, testing, and administrative procedures.

The guidance in Appendix A to RG 1.166 is followed if the instrumentation is discovered to have been out of service during an earthquake.

3.7.4.6 Comparison with RG 8.8

Acceleration sensors are installed such that occupational radiation exposures associated with their location, installation, and maintenance are maintained as Low as is reasonably achievable consistence with 10 CFR 20.1101(b) and RG 8.8, “Information Relevant to Ensuring that Occupational Radiation Exposures at Nuclear Power Stations Will Be as Low as Is Reasonably Achievable,” and as discussed in Section 12.3.

(Sheet 2 of 2)

Structure	Seismic Category/Evaluation	Design/Evaluation Basis	Design Basis Earthquake (1)	Limit State (2)
Service Building Structure	Seismic Category II	IBC		
	To meet II/I Seismic Interaction requirements (4)	ASCE/SEI 43 and ASCE/SEI 4	SSE	LS-C
Reactor Auxiliary Structures	Seismic Category II	IBC		
	To meet II/I Seismic Interaction requirements (4)	ASCE/SEI 43 and ASCE/SEI 4	SSE	LS-C
Equipment Structures	Non-Seismic	IBC		

Notes:

1. SSE is defined in Subsection 3.7.1.
2. Limit States per ASCE/SEI 43-19:
   - LS-D essentially elastic response
   - LS-C response with limited permanent deformations
3. The RWB is designed in accordance with the radioactive waste management requirements for Seismic Category RW-IIa from RG 1.143.
4. Proximity of this building to the Seismic Category I RB structure requires seismic interaction evaluation to SSE.

3.8 Design of Seismic Category I Structures

The BWRX-300 Seismic Category I structures consist of the Reactor Building (RB), the containment, and containment internal structures, otherwise referred to as the integrated RB structures.

The BWRX-300 containment design is discussed in Subsections 3.8.1 and 3.8.2, with Subsection 3.8.1 focusing on the Steel-Plate Composite Containment Vessel (SCCV) portion of the containment and Subsection 3.8.2 focusing on the containment steel closure head and other Class MC components of the containment.

Internal structures housed in the containment are discussed in Subsection 3.8.3 and include the pedestal that supports the Reactor Pressure Vessel (RPV) and structures supporting piping and equipment within the containment.

The design of the RB structure outside of containment is discussed in Subsection 3.8.4, while the design of the common steel-plate composite mat foundation supporting the integrated RB is discussed in Subsection 3.8.5.

Subsections 3.8.4 and 3.8.5 also provide the design requirements for the adjacent Power Block structures and their foundations. For the location of these Power Block structures, refer to Section 1.2. General arrangement drawings of the RB and containment are also presented in Section 1.2.

In the following subsections, reference to the integrated RB is inclusive of the RB, containment, and containment internal structures whereas RB is used to refer to the RB structure outside of containment.

3.8.1 Steel-Plate Composite Containment Vessel

The BWRX-300 uses a traditional containment for the ultimate containment of radioactive materials for various postulated events. The configuration of the containment is shown in Figure 3.8-1. It comprises a SCCV, a steel containment closure head and other Class MC components. As shown in Figure 3.8-1, the BWRX-300 containment is completely enclosed within the RB.

The primary functions of the containment are:

1. To enclose and support the RPV and its connected piping systems.

2. To act as a leak-tight pressure boundary confining radioactive substances in different plant states, including normal operation, anticipated operational occurrences, Design Basis Accidents (DBAs) and Design Extension Conditions (DECs).

3. To provide radiation shielding to limit radiation dose within the applicable regulatory standards in different plant states.

4. To provide, in conjunction with the surrounding RB, protection for plant safety equipment and systems against external hazards and human induced events.

The following subsections present the analysis and design requirements for the SCCV portion of the containment.

3.8.1.1 Description of the Steel-Plate Composite Containment Vessel

The BWRX-300 SCCV structure consists of a cylindrical wall, mat foundation, and top slab. The SCCV is constructed using steel-plate composite modules with diaphragm plates referred to as Diaphragm Plate Steel-Plate Composite (DP-SC) modules. The diaphragm plates of DP-SC modules have holes to allow the flow of concrete and are used, along with headed studs steel anchors, to provide the composite action between the steel faceplates and the concrete core.

The SCCV DP-SC modules, including the inner and outer faceplates, diaphragm plates, steel headed stud anchors and concrete infill are part of the containment pressure boundary, with the modules inner faceplate also serving as a leak-tight liner.

As shown in Figure 3.8-1, the SCCV structure includes two airlocks (see Subsection 3.8.2.1.2), penetrations (see Subsection 3.8.2.1.3), and other safety components, such as the corium shield installed on the lower portion of the SCCV and RPV pedestal. The corium shield protects the mat foundation and RPV pedestal from damage following core melt by preventing contact between the molten core and the DP-SC faceplates and concrete during severe accident conditions.

Besides the connection at the common mat foundation, the SCCV and the RB structures are also connected at the top slab and through the RB wing walls and floor slabs at intermediate floor levels as shown in Figure 3.8-1. The SCCV top slab directly supports the reactor cavity pool and portions of the Ultimate Heat Sink (UHS) in the RB, such as the fuel pool, equipment pool and isolation condenser inner pools.

A description of the steel containment closure head that covers the opening in the SCCV top slab over the RPV is provided in Subsection 3.8.2.1.1.

3.8.1.2 Applicable Codes, Standards, and Specifications

Codes, standards, specifications, and regulations applicable for the analysis, design, fabrication, construction, testing, and Inservice Inspection (ISI) of the SCCV are listed in NEDC-33926P, “BWRX-300 Steel-Plate Composite (SC) Containment Vessel and Reactor Building Structural Design,” (Reference 3.8-1). Conformance to USNRC regulatory requirements and guidance is discussed in Chapter 1, Section 3.1, and Section 2.0 of NEDC-33926P.

As stated in Section 3.1, the design, fabrication, construction, testing, and ISI of the SCCV conforms to 10 CFR 50 and complies with the provisions of:

GDC 1 - A design, manufacturing, and operating quality program is established for the SCCV commensurate with the importance of its safety functions as discussed in Subsection 3.8.1.6.

GDC 2 - The SCCV is designed to withstand the effects of a Safe Shutdown Earthquake (SSE) and tornadoes, hurricanes, floods, as applicable, without loss of capability to perform safety functions as discussed in Subsection 3.8.1.3.

GDC 4 - The SCCV is designed to accommodate the effects of and be compatible with environmental conditions associated with normal operation, maintenance, testing, and postulated accidents, including LOCAs as discussed in Subsection 3.8.1.3.

GDC 16 - The SCCV, including the containment closure head, access openings and penetrations, is designed to provide a leak-tight barrier and to contain the containment design pressure during design basis events as discussed in Subsections 3.8.1.2.1, 3.8.1.3, 3.8.1.4.5 through 3.8.1.4.7 and 3.8.1.7.

GDC 50 - The SCCV, including the containment closure head, access openings and penetrations, is designed to accommodate, without exceeding the design leakage rate and with sufficient margin, the calculated pressure and temperature conditions resulting from LOCA as discussed in Subsection 3.8.1.3 and 3.8.1.4.5 through 3.8.1.4.7.

GDC 51 - The SCCV, including the containment closure head, access openings and penetrations, is designed with sufficient margin to assure that, under operating, maintenance, testing, and postulated accident conditions, (1) ferritic materials behave in a nonbrittle manner and (2) the probability of rapidly propagating fracture is minimized. The design reflects consideration of service temperatures and other conditions of the containment boundary material during operation, maintenance, testing, and postulated accident conditions, and the uncertainties in determining (1) material properties, (2) residual, steady-state, and transient stresses, and (3) size of flaws, as applicable, as discussed in Subsection 3.8.1.4 and Subsection 3.8.1.7.

GDC 52 - The SCCV, including the containment closure head, access openings and penetrations is designed with provisions to conduct periodic integrated leakage rate testing at containment design pressure as discussed in Subsection 3.8.1.7.2 and 6.2.

GDC 53 - The containment is designed to permit (1) appropriate periodic inspection of all important areas such as penetrations, (2) an appropriate surveillance program, and (3) periodic testing at containment design pressure of the leak tightness of penetrations as discussed in Subsection 3.8.1.7.

Section 3.1 summarizes compliance with GDC.

The materials, analysis, design, fabrication, construction, inspection, examination and testing of the SCCV are in accordance with the provisions of Section 6.0 of NEDC-33926P. These provisions are adapted from American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code (BPVC), Section III, “Rules for Construction of Nuclear Facility Components,” Division 2, “Code for Concrete Containments,” Subsection CC, “Concrete Containments,” CC-1000 through CC-6000, including Division 2 Appendices (Reference 3.8-2) and changed based on analytical and engineering principles, including use of experimental results, to apply to a DP-SC containment vessel. Additional analysis and design guidance of

SRP 3.8.1, “Concrete Containment,” and RG 1.136, “Design Limits, Loading Combinations, Materials, Construction, and Testing of Concrete Containments,” for concrete containments are also met, as applicable.

The applicable sections of the ASME BPVC, such as Section II, “Materials,” (Reference 3.8-3); Section III, Subsection NCA, “General Requirements for Division 1 and Division 2,” (Reference 3.8-4); Section V, “Non-Destructive Examination,” (Reference 3.8-5); and Section IX, “Qualification Standard for Welding, Brazing, and Fusing Procedures; Welders; Brazers; and Welding, Brazing, and Fusing Operators,” (Reference 3.8-6) are followed to the extent they apply to a DP-SC containment without reinforcing steel or tendons. ASME BPVC, Section XI, “Rules for Inservice Inspection of Nuclear Power Plant Components,” Division 1, “Rules for Inspection and Testing of Components of Light-Water-Cooled Plants,” incorporated by reference in 10 CFR 50.55a(g)(4) 18 months before the date of issuance of the operating license for the initial 120-month ISI interval as described in 10 CFR 50.55a(g)(4)(i), (Reference 3.8-7) is followed for the containment pre-service and periodic ISI and testing program.

3.8.1.2.1 Containment Jurisdictional Boundary

The BWRX-300 design codes jurisdictions are illustrated in Figure 3.8-2. As defined in Section 6.1 of NEDC-33926P, and shown in Figure 3.8-2, the SCCV boundary extends to the:

1. Outside diameter of the SCCV wall from mat foundation to containment top slab including the welds connecting the SCCV with the RB structural members.

2. Portion of the mat foundation under SCCV including the welds connecting the SCCV portion of the mat foundation with the remaining part of the RB mat foundation.

3. Containment top slab from containment closure head opening to the outside diameter of the SCCV including the welds connecting the slab with the RB structural members.

The SCCV along with the containment closure head, access openings and penetrations, provide the primary containment function as a leak-tight pressure boundary confining radioactive substances in different plant states. Although the internal RPV pedestal and other containment internal structures are completely within the SCCV, these internal structures are non-pressure retaining structures and are designed per the requirements of the American National Standard Institute (ANSI)/American Institute of Steel Construction (AISC) N690, “Specification for Safety-Related Steel Structures for Nuclear Facilities,” (Reference 3.8-8). The design of welds connecting the containment internal structures to the containment pressure boundary is per Section 6.11 of NEDC-33926P and follows the quality assurance, welding procedures and inspection requirements of Sections 6.15 and 6.16 of NEDC-33926P. The connections of the RB walls and floors to the outside face of the SCCV wall are designed per Section 5.0 of NEDC-33926P, with the exception of attachment welds. Attachment welds connecting the RB walls and floors to the SCCV outside face are designed per Section 6.11 of NEDC-33926P and follow the quality assurance, welding procedures and inspection requirements of Sections 6.15 and 6.16 of NEDC-33926P.

3.8.1.3 Loads and Loading Combinations

The BWRX-300 containment is analyzed and designed for all credible conditions of loading, including normal loads, preoperational testing loads, loads during severe environmental conditions, loads during extreme environmental conditions, and loads during abnormal plant conditions. Load combinations considered in the design consider the probability of occurrence, loading time history and sequence of loads, as applicable.

Subsections 3.8.1.3.1 through 3.8.1.3.5 describe loads used in the design of the BWRX-300 containment. These loads are applicable to the SCCV, containment closure head and other Class MC components of the containment. Containment design loads are in accordance with the provisions of ASME BPVC, Section III, Division 1, Subsection NE, “Class MC Components,” (Reference 3.8-9) and ASME BPVC, Section III, Division 2, and are consistent with the guidance of SRP 3.8.1 and SRP 3.8.2, “Steel Containment.” Loads resulting from the application of prestress and from relief valve or other high-energy device actuation are not considered in the design as these loads are not applicable to the BWRX-300 containment.

Load combinations used in the design of the SCCV are provided in Subsection 3.8.1.3.6. Load combinations used in the design of the containment closure head and other Class MC components are presented in Subsection 3.8.2.3.2.

SCCV design loads include RPV reactions due to seismic loads, LOCA loads, and acoustic loads, as well as containment penetrations, brackets, and attachment loads. The connections between the containment, RB, and containment internal structures in the integrated Finite Element (FE) model ensure a proper transfer of RPV reactions and other loads applied on the RB and containment internal structures to the SCCV structure.

3.8.1.3.1 Normal Loads

1. Dead load (D) which includes permanent dead weight of structural and shielding elements, and permanently located equipment.

2. Hydrostatic pressure of liquids in various pools (F).

3. Live loads (L, L_o) which include moveable equipment loads and other loads that vary in intensity and occurrence.

4. Indirect snow (S) and rain (R) Loads.

5. Thermal (T_o) effects and loads during normal operating, startup, or shutdown conditions.

6. Pressure (P_o) loads resulting from the pressure difference between the interior and exterior of the containment, considering both interior pressure changes due to heating or cooling and exterior atmospheric pressure variations. External pressure loads resulting from pressure variation either inside or outside the containment (P_v), as defined in ASME BPVC, Section III, Division 2, CC-3221.1, are considered under the P_o load case.

7. Pipe reactions (R_o) during normal operating or shutdown conditions based on the most critical transient or steady-state conditions.

8. Construction loads applied to the containment from start to completion of construction. The definitions for D, L and T_o given above are applicable, but are based on actual construction methods and/or conditions.

9. Indirect lateral soil and groundwater pressure loads (H).

3.8.1.3.2 Preoperational Testing Loads

1. Test thermal loads (T_t) due to thermal effects during the Structural Integrity Test (SIT) or Integrated Leak Rate Test (ILRT).

2. Test pressure loads (P_t) applied during the SIT or ILRT.

3.8.1.3.3 Severe Environmental Loads

1. Indirect design wind load (W) defined in Subsection 3.3.1.

3.8.1.3.4 Extreme Environmental Loads

1. Indirect extreme wind loads (W_t), including tornado and hurricane-generated missiles, defined in Subsections 3.3.2 and 3.5.

2. SSE seismic loads (E_s) determined for Clinch River Nuclear (CRN) site-specific conditions considering Soil-Structure Interaction (SSI) effects, as discussed in Section 3.7, and include associated hydrodynamic loads and dynamic incremental soil pressures.

3.8.1.3.5 Abnormal Plant Loads

1. Accidental thermal effects (T_a) due to LOCA.

2. Accidental pressure loads (P_a) within the containment generated by a LOCA.

3. Accidental Pipe reaction loads (R_a) that consist of pipe reactions (including R_o) from thermal conditions generated by DBAs such as LOCA and SSE.

4. Local effects on containment due to LOCA (R_r) and blast loads (R_b) which includes:

   - R_{rr} load on the containment generated by the reaction of a ruptured high-energy pipe during the postulated event of the DBA
   - R_{rj} load on the containment generated by the jet impingement from a ruptured high-energy pipe during the postulated event of the DBA
   - R_{rm} load on the containment resulting from the impact of a ruptured high-energy pipe during the DBA

- Additional blast loads that may result from a postulated instantaneous break of a large pipe that could occur prior to jet loads

5. Internal flooding loads resulting from a DBA (H_a).

6. Other externally and internally generated missiles and design basis threats discussed in Section 3.5, as applicable.

3.8.1.3.6 Load Combinations

The SCCV is designed for the load combinations and load factors presented in Table 3.8-1. Load combinations used in the design of the SCCV are in accordance with ASME BPVC, Section III, Division 2, CC-3230, supplemented by RG 1.136 and are consistent with the guidance of SRP 3.8.1.

3.8.1.4 Design and Analysis Procedures

3.8.1.4.1 Analytical Method

The RB, containment, containment internal structures, and their common mat foundation are analyzed as one integrated structure. Analysis procedures for the integrated structure, including a description of the Three-Dimensional (3D) model and computer codes used in the analysis, and assumptions made on boundary conditions, are discussed in Subsection 3.8.4.1.4. Details of the integrated RB FE model are provided in Appendix 3B.

As mentioned in Subsection 3.8.1.1, the SCCV and RB structures are connected at several locations. The connections between the SCCV and the RB members in the integrated RB FE model are modeled to reflect the appropriate load transfer for vertical, lateral, and thermal loads. The SCCV connections are modeled and designed as discussed in Sections 5.6 and 5.11 of NEDC-33926P, respectively. For more details on the SCCV connections, refer to Appendix 3B and Appendix 3F.

Treatment of Axisymmetric and Non-axisymmetric Loads

ANSYS, the FE analysis software used to model and analyze the integrated RB structures, including the SCCV (see Appendix 3I) evaluates the effects of the axisymmetric and non-axisymmetric loads applied on the 3D FE model by calculating the distribution of internal forces on the structural members.

The SCCV is shielded from the design wind, tornado, and hurricane by the RB, which completely encloses the structure. Forces from the design wind, tornado and hurricane are transmitted to the SCCV through the RB connections.

Indirect subgrade pressures are also transmitted to the SCCV through the RB connections. These pressures are obtained from the SSI analyses of the integrated RB discussed in Subsection 3.7.2. Methodology used to validate the subgrade pressure loads on the integrated RB is per Section 5.1.3 of NEDO-33914-A, “BWRX-300 Advanced Civil Construction and Design Approach,” (Reference 3.8-10).

Major Penetrations

The SCCV major penetrations are described in Subsection 3.8.2.1. These penetrations are included in the global integrated RB FE model used in the SSI analyses as stated in Subsections 3.7.2.3.1 and 3.8.4.1.4.

The state of stress and behavior of the SCCV around these openings is determined by use of acceptable analytical techniques, including but not limited to, the use of refined local FE models incorporating the imposed displacements calculated from the global integrated RB FE model discussed in Subsection 3.8.4.1.4.

Variation in Physical Material Properties

The effects of variation in assumptions and material properties on the integrated RB SSI analysis results are considered as discussed in Subsection 3.7.2.9.1.

Use of Vent Holes

Vent holes may be used in the SCCV and RB steel-plate composite structures if needed. If used, the design of vent holes will comply with the requirements of Sections 5.14 and 6.21 of NEDC-33926P.

3.8.1.4.2 Design Method

The SCCV structure design conforms to the requirements of Section 6.0 of NEDC-33926P and meets the acceptance criteria discussed in Subsection 3.8.1.5. As stated in NEDC-33926P, the design guidelines for the SCCV are adapted from ASME BPVC, Section III, Division 2, for concrete containments using current research data for steel-plate composite structures.

Membrane forces, shear forces and bending moments used in the design of the SCCV structure are obtained from the linear elastic SSI analyses for the integrated RB FE model discussed in Subsection 3.8.4.1.4, for the loads and load combinations defined in Subsection 3.8.1.3. Appendix 3F presents design demands for critical SCCV sections identified per the criteria provided in Subsection 3.8.4.1.4.

3.8.1.4.3 Creep, Shrinkage, and Cracking of Concrete

The analysis of the SCCV considers the effects of creep, shrinkage, and cracking of concrete on the redistribution of forces and moments.

As stated in Subsection 3.7.2.3.1, stiffness calculations for structural modeling account for the expected state of stress and level of cracking for different loading conditions during normal operation and accident conditions, including accident thermal loading.

The effective stiffnesses, geometric and material properties, for operational and accidental conditions, of SCCV elements are computed using the equations in Section 5.5 of NEDC-33926P.

3.8.1.4.4 Tangential Shears/Stresses

Tangential (membrane) shears are captured in the 3D FE model of the SCCV. SCCV sections capacities are computed as discussed in Section 6.8 of NEDC-33926P.

3.8.1.4.5 Ultimate Capacity of Steel-Plate Composite Containment Vessel

The ultimate pressure capacity of the containment structure, including the SCCV, containment closure head, access openings and penetrations, is determined to ensure its structural integrity and leak tightness under DEC internal pressure loads following the guidance of SRP 3.8.1 and RG 1.216, “Containment Structural Integrity Evaluation for Internal Pressure Loadings Above Design Basis Pressure.”

The containment ultimate pressure capacity is obtained from the results of static FE analysis performed as described in Section 6.23.1 of NEDC-33926P, consistent with the guidance of Regulatory Position 1 of RG 1.216.

3.8.1.4.6 Steel-Plate Composite Containment Vessel Robustness Against Combustible Gas Pressure Loads

As stated in NEDC-33911P-A, “BWRX-300 Containment Performance,” (Reference 3.8-11), and in Subsections 6.2.5 and 15.5.4.5, the containment design prevents combustible gases from creating a concern for deflagration in the containment during a DBA.

The containment structural robustness against DEC combustible gas pressure loads is evaluated using the methodology discussed in Section 6.23.2 of NEDC-33926P.

3.8.1.4.7 Steel-Plate Composite Containment Vessel Behavior Following a Severe Accident

In accordance with SECY-93-087, “Policy, Technical, and Licensing Issues Pertaining to Evolutionary and Advanced Light-Water Reactor (ALWR) Designs,” the BWRX-300 containment under the more likely severe accident conditions:

- Maintains its role as a reliable leak-tight barrier for approximately 24 hours following the onset of core damage.
- Continues to provide a barrier against the uncontrolled release of fission products following the initial 24-hour period.

The containment response to identified severe accidents is evaluated in the Final Safety Analysis Report using the methodology provided in Regulatory Position 3 of RG 1.216 and as described in Section 6.23.3 of NEDC-33926P.

3.8.1.4.8 Corrosion Prevention

In accordance with Section 5.15 of NEDC-33926P, the corrosion protection of the SCCV DP-SC modules is met by one or a combination of the following approaches to meet the design life and decommissioning time of the plant:

- Corrosion tolerance by adding a sacrificial thickness
- Protective paint system suitable to the surrounding environment
- Membrane coating system
- Impressed Current Cathodic Protection

The additional sacrificial thickness for corrosion tolerance is not considered in the DP-SC modules strength or stiffness estimates.

RG 1.54, “Service Level I, II, III, and In-Scope License Renewal Protection Coatings Applied to Nuclear Power Plants,” and ASTM International (ASTM) D5144, “Standard Guide for Use of Protective Coating Standards in Nuclear Power Plants,” (Reference 3.8-12) are used for application, maintenance, and qualification of permanent corrosion protective coatings, as applicable.

3.8.1.5 Structural Acceptance Criteria

The acceptance criteria for the design of the SCCV are presented in Table 3.8-2a and Table 3.8-2b. Following the guidance of SRP 3.8.1, Subsection II.5 and as stated in Section 6.6 of NEDC-33926P, these allowables are based on criteria in Tables CC-3432-1 and CC-3432-2 of ASME BPVC, Section III, Division 2, Subsection CC modified to include the allowable stresses for the steel component of DP-SC modules. The stress/strain acceptance criteria in Table 3.8-2a and Table 3.8-2b allow the SCCV to remain elastic under service load combinations and below the range of general yield under factored loads.

The seismic design criteria for the BWRX-300 containment, including the SCCV, containment closure head and other Class MC components are summarized in Table 3.7-1. The seismic design of the SCCV considers Limit State LS-D response in accordance with American Society of Civil Engineers (ASCE)/Structural Engineering Institute (SEI) 43-19, “Seismic Design Criteria for Structures, Systems, and Components in Nuclear Facilities,” (Reference 3.8-13), ensuring an essentially elastic response when subjected to SSE.

The BWRX-300 SCCV is designed for impulsive and impactive loads per the guidance of Appendix A of SRP 3.8.1. ASME BPVC, Section III, Division 2 provisions are not fully applicable to the DP-SC containment. Design allowable stresses and deformation limits developed for the SCCV design are provided in Section 6.10 of NEDC-33926P.

3.8.1.6 Materials, Quality Control, and Special Construction Techniques

3.8.1.6.1 Materials

Materials used in the construction of the SCCV are in accordance with Section 6.2 of NEDC-33926P and RG 1.136.

To ensure the acceptability of the DP-SC modules for the construction of the SCCV, the NEDC-33926P design requirements are supported by results from a test program performed under the National Reactor Innovation Center (NRIC) Advanced Construction Technology project in the United States. Mockups are used to demonstrate the efficiency of fabrication, installation, and construction processes for use of DP-SC modules for nuclear applications.

Properties of materials used in the construction of the SCCV are provided in the following subsections.

Concrete Infill

To enhance shielding, a high-density self-consolidating concrete designed in accordance with RG 1.69, “Concrete Radiation Shields and Generic Shield Testing for Nuclear Power Plants,” is used in the SCCV wall.

The design compressive strength for the high-density self-consolidating concrete used for the construction of the SCCV is determined as described in Section 5.2.1 of NEDC-33926P.

Concrete is batched and placed in accordance with Sections 6.2.1 and 6.15 of NEDC-33926P. Concrete and concrete constituents are examined and tested in accordance with Section 6.16 of NEDC-33926P. Supplementary concrete sampling requirements are used as described in Section 3.2.2.1 of NEDO-33914-A to address the effect of small volume of concrete placed.

Aggregates in concrete subjected to elevated temperatures for long periods of time do not contain pyretic materials.

Steel Materials

DP-SC steel components conform to the following:

- Steel faceplates/diaphragm plate: ASME SA-738 Grade B or SA-537 Class 1 or Class 2, or ASTM A709/A709M-21, “Standard Specification for Structural Steel for Bridges,” Grade HPS 70W (Reference 3.8-14), per ASME BPVC, Code Case N-763, “ASTM A709-06, Grade HPS 70W (HPS 485W) Plate Material Without Postweld Heat Treatment as Containment Liner Material or Structural Attachments to the Containment Liner, Subsection CC, Section III, Division 2,” (Reference 3.8-15)
- Studs: ASTM A108 Type B , “Standard Specification for Steel Bar, Carbon and Alloy, Cold-Finished,” (Reference 3.8-16), as permitted by ASME BPVC, Section III, Division 2, Subsection CC, Mandatory Appendix D2-1, Table D2-1-2.2 and meeting the strength requirements of ASME BPVC, Section III, Division 2, Subsection CC, CC-2711, Table CC-2623.2-1

Structural Steel and Appurtenances

The structural steel and other appurtenances for the SCCV other than the primary DP-SC steel components covered above conform to the following:

- Structural steel embedded plate and attachments: ASTM A572 Grade 50, “Standard Specification for High-Strength Low-Alloy Columbium-Vanadium Structural Steel,” (Reference 3.8-17), per ASME BPVC, Code Case N-632, “Use of ASTM A572 Grades 50 and 65 for Structural Attachments to Class CC Containment Liners, Section III, Division 2,” (Reference 3.8-18)
- Penetrations: ASME SA-516 Grade 60 or Grade 70, or SA-537 Class 2

Welding Materials

SCCV welding materials conform to the requirements of Section 6.0 of NEDC-33926P and ASME BPVC, Section IX.

Coatings

Corrosion protective coatings applied on the SCCV steel face plates are discussed in Subsection 3.8.1.4.8.

3.8.1.6.2 Quality Control

Quality control procedures are established for the SCCV in the construction, fabrication and installation specifications and implemented during the fabrication, construction, installation, and inspection stages.

These specifications cover the fabrication, furnishing, and installation of each structural item and specifies the inspection and documentation requirements to ensure that the requirements of ASME BPVC, Section III, Division 2, CC-4000 and CC-5000, RG 1.28, “Quality Assurance Program Criteria (Design and Construction)” and RG 1.136 are met.

Procedures governing the design, fabrication, construction, installation, and inspection of the SCCV are developed in compliance with the GEH quality assurance program described in Chapter 17.

Welded Construction and Examinations

Refer to Subsection 3.8.1.2.1 for quality control procedures used for attachment welds connecting the SCCV to the RB walls and floors.

3.8.1.6.3 Special Construction Techniques

The SCCV is constructed using modular construction technique as discussed in Subsection 3.8.4.1.6.

The SCCV construction requirements are in accordance with Sections 6.15 and 6.16 of NEDC-33926P.

3.8.1.7 Testing and Inservice Surveillance Requirements

A pre-service and periodic ISI and testing program is established for the SCCV to meet the requirements of ASME BPVC, Section XI, Subsections IWE and IWL, as per 10 CFR 50.55a(b)(2)(viii) and (b)(2)(ix).

3.8.1.7.1 Structural Integrity Test

The SCCV pre-service SIT plan and instrumentation complies with Section 6.17 of NEDC-33926P, and with RG 1.136 and RG 1.216.

In accordance with Section 6.17 of NEDC-33926P, deformation and strain measurements are made to evaluate the behavior of the prototype SCCV, as defined per ASME BPVC, Section III, CC-6150, and confirm that the actual structural response is within the limits predicted by analysis.

3.8.1.7.2 Pre-Operational and Inservice Integrated Leak Rate Testing

The SCCV is designed such that periodic ILRT can be conducted as discussed in Subsection 6.2.6.

3.8.1.7.3 Containment Pre-Service and Inservice Inspection

The SCCV pre-service and periodic ISI plan is in accordance with Sections 6.17 and 6.22 of NEDC-33926P, respectively, and meets the requirements of ASME BPVC, Section XI.

3.8.2 Class MC Steel Components of the BWRX-300 Containment

The Class MC components of the BWRX-300 containment comprise the containment closure head, the two containment airlocks and the containment penetrations.

3.8.2.1 Description of the Class MC Steel Components

3.8.2.1.1 Containment Closure Head

The containment closure head is a removable steel head anchored to the SCCV top slab using a pair of mating flanges. The containment closure head is part of the containment pressure boundary and forms part of the reactor cavity pool. The containment closure head is designed for removal during reactor refueling and for replacement prior to reactor operation.

Provisions are made for testing the flange seals to ensure the containment closure head can perform its pressure retaining functions. Stainless steel cladding is fixed to the outer surface of the containment closure head to protect it from the water in the reactor cavity pool. The cladding thickness is determined as discussed in Subsection 3.8.2.4.

A structural overview of the containment closure head is shown in Figure 3.8-1 and Figure 3.8-3.

3.8.2.1.2 Containment Airlocks

As shown in Figure 3.8-1, two airlocks are provided in the SCCV structure to provide access to the upper and lower portions of the containment. These airlocks serve the dual purpose of allowing personnel access to the containment and for movement of equipment. Figure 3.8-4 provides a structural overview of an airlock and its interface with the SCCV wall.

Each containment airlock has two pressure-seated doors interlocked to prevent simultaneous opening of both doors, and to ensure that one door is completely closed before the opposite door can be opened. The door operation is designed and constructed so either door may be operated from inside the containment, inside the lock, or from outside the containment. Also, each airlock has a barrel, which is an inner round portion that is slid into the fixed portion of the sleeve that is embedded in the SCCV wall. The barrel of the airlock can be removed if large equipment needs to be transported during outages.

3.8.2.1.3 Penetrations

Figure 3.8-5 provides a structural overview of a typical penetration and its interface with the SCCV.

The major piping penetrations through the SCCV are associated with main steam and feedwater lines. Sleeve length for hot penetrations is designed to meet the concrete temperature limitations specified in Section 6.5.1 of NEDC-33926P. SCCV electrical penetrations are sealed to the SCCV pressure boundary.

3.8.2.2 Applicable Codes, Standards, and Specifications

The containment closure head, access openings and penetrations are part of the containment pressure boundary, and their design, fabrication, construction, testing, and ISI conform to 10 CFR 50 and comply with the provisions of GDC 1, 2, 4, 16, 50, 51, 52 and 53 as discussed in Section 3.1 and Subsection 3.8.1.2.

The containment closure head, access openings and penetrations are analyzed, designed, fabricated, constructed, inspected, and tested following the provisions of ASME BPVC, Section III, Division 1, Subsection NE; Section XI, Subsection IWE; and 10 CFR 50 Appendix J in conformance with SRP 3.8.2.

The code jurisdictional boundary for application of ASME BPVC, Section III, Division 1, Subsection NE, Class MC to the containment closure head, access openings and penetrations is shown in Figure 3.8-3, Figure 3.8-4, and Figure 3.8-5, respectively.

Metal components backed by concrete are designed in accordance with Section 6.0 of NEDC-33926P.

3.8.2.3 Loads and Loading Combinations

3.8.2.3.1 Design Loads

Class MC components are designed for loading conditions applicable for the containment structure. Refer to Subsection 3.8.1.3 for the description of loads used in the design of the SCCV that are also applicable for the design of the containment Class MC components.

3.8.2.3.2 Design Load Combinations

Load combinations and associated load factors used in the design of the containment Class MC components are in conformance with SRP 3.8.2 and RG 1.57, “Design Limits and Loading Combinations for Metal Primary Reactor Containment System Components,” except for MC components backed by concrete are per the alternative design approach discussed in Sections 4.0 and 6.0 of the NEDC-33926P.

Table 3.8-3 and Table 3.8-4 summarize the load combinations and associated load factors used in the design of the containment closure head and other Class MC components, respectively.

As shown in Table 3.8-3 and Table 3.8-4, Class MC components combined loadings are categorized according to Level A, C and D service limits as defined in NE-3113. Because the Operating Basis Earthquake (OBE) is set at one-third of the SSE for design purposes as described in Section 3.7.1, OBE load combinations are not considered in the design. The OBE load combination involving post-flooding conditions is considered for the design of Class MC components, excluding containment closure head, in accordance with SRP 3.8.2. OBE loads are also considered for cyclic loading considerations following the guidance of SRP 3.8.2.

Metal components backed by concrete are designed for the load combinations and associated load factors as summarized in Table 3.8-1.

3.8.2.4 Design and Analysis Procedures

Analysis and design procedures for the containment closure head, access openings and penetrations, are presented in Subsections 3.8.2.4.1, 3.8.2.4.2 and 3.8.2.4.3, respectively.

The design of the Class MC steel components meets the acceptance criteria discussed in Subsection 3.8.2.5, including buckling and fatigue evaluations as required.

The design by analysis utilizes demands obtained from the linear elastic SSI analyses for the integrated RB FE model discussed in Subsection 3.8.4.1.4, for the loads and load combinations defined in Subsection 3.8.1.3. For the treatment of non-axisymmetric and localized loads on Class MC components, refer to Subsection 3.8.1.4.1.

Corrosion prevention methods considered for the containment closure head and Class MC components include the use of protective coatings and sacrificial thicknesses determined in accordance with NE-3121. The thickness of the cladding fixed to the wetted surface of the

containment closure head is determined in accordance with NE 3122. The guidance of RG 1.54 and ASTM D5144 are used as applicable for the application, maintenance, and qualification of corrosion protective coatings.

Effects of containment penetrations on the containment internal ultimate pressure capacity are considered as discussed in Subsection 3.8.1.4.5 and in Section 6.23.1 of NEDC-33926P.

3.8.2.4.1 Containment Closure Head

Design procedures for the containment closure head are shown in Figure 3.8-6.

The containment closure head is analyzed using ANSYS and ACS SASSI computer programs and manual calculation. The stresses, including discontinuity stresses induced by the combination of external pressure or internal pressure, dead load, live load, thermal effects, and seismic loads, are evaluated. Minimum thickness evaluations, including local strengthening of the containment closure head at locations of attachments and openings, are performed in accordance with NE-3100 and NE-3300. The required analyses and limits for the resulting stress intensities for the containment closure head are in accordance with ASME BPVC, Section III, Division 1, Subsection NE, NE-3200.

Following the guidance of Subsection II.4 of SRP 3.8.2, the evaluation of the containment pressure capacity considers buckling of the containment closure head under internal pressure as one of its limiting conditions. The compressive stress within the knuckle region caused by the internal pressure and the compression in other regions caused by other loads are limited to the allowable compressive stress values in accordance with NE-3222 or Code Case N-284-4, “Metal Containment Shell Buckling Design Methods, Class MC, TC, SC Construction, Section III, Division 1 and Division 3,” (Reference 3.8-19).

The containment closure head is also evaluated for fatigue, with the total number of stress cycles considered in the fatigue evaluation following the requirements of NE-3221.5(d). Because the containment closure head is submerged in the reactor cavity pool and can be exposed to water temperature above 50°C during accident, the fatigue evaluation of the containment closure head also follows the guidance of RG 1.207, “Guidelines for Evaluating Fatigue Analyses Incorporating the Life Reduction of Metal Components Due to the Effects of the Light-Water Reactor Environment for New Reactors.”

3.8.2.4.2 Containment Airlocks

Design procedures for the containment airlocks are shown in Figure 3.8-7.

The containment airlocks are analyzed using ANSYS and/or manual calculation based on handbook formulas and tables. The discontinuity stresses induced by the combination of external, dead, and live loads, including the effects of earthquake loadings are evaluated. Minimum thickness evaluations for the containment airlocks are in accordance with NE-3100 and NE-3300. The airlocks required analyses and limits for the resulting stress intensities are in accordance with NE-3200 including buckling evaluation per Code Case N-284-4 and fatigue evaluation as required.

The design and detailing of airlock components backed by concrete also meet the requirements of Section 6.12 of NEDC-33926P.

3.8.2.4.3 Penetrations

Design procedures for the containment penetrations are shown in Figure 3.8-7.

Penetrations are subjected to various combinations of piping reactions, mechanical, thermal, and seismic loads transmitted through the SCCV structure. The resulting forces due to various load combinations are combined with the effects of external and internal pressures. Penetrations are analyzed using ANSYS and/or manual calculation based on handbook formulas and tables for applicable loads and load combinations. Minimum thickness evaluations for the containment penetrations are in accordance with NE-3100 and NE-3300. The penetration required analysis and associated stress intensity limits are in accordance with NE-3200, including buckling evaluation per Code Case N-284-4 and fatigue evaluation as required.

The design and detailing of penetration components backed by concrete also meet the requirements of Section 6.12 of NEDC-33926P.

3.8.2.5 Structural Acceptance Criteria

The acceptance criteria for the design of the Class MC components of the containment are the allowable stress limits specified in NE-3220. Seismic design criteria for the containment Class MC components are the same as those for the SCCV described in Subsection 3.8.1.5.

The structural acceptance criteria for the post-flooding condition, which is only applicable for Class MC components other than the containment closure head, is in accordance with SRP 3.8.2. Table 3.8-5 and Table 3.8-6 summarize the acceptance criteria for testing, design, Service Level A, C and D, and Post-flooding conditions, as applicable, for the containment closure head and other Class MC components, respectively.

Stability against compression buckling is in accordance with NE-3222.1.

3.8.2.6 Materials, Quality Control, and Special Construction Techniques

3.8.2.6.1 Materials

Steel materials used in the fabrication of the containment closure head and other Class MC components of the containment are in accordance with NE-2000.

Structural steel and other appurtenances for the containment closure head and other Class MC components conform to the following:

- Structural steel: ASME SA-516 Grade 60 or 70, SA-537 Class 1 or Class 2, or SA-738 Grade B

- Non-pressure-retaining attachments: ASTM A572 Grade 50 as permitted by ASME BPVC, Section III, “Rules for Construction of Nuclear Facility Components,” Division 1, Subsection NF, “Supports,” (Reference 3.8-20) referenced by ASME BPVC, Section III, Division 1, Subsection NE
- Stainless steel cladding: ASME SA-264 steel-clad plate alloy and SA-240 Type 304L alloy for general application in accordance with ASME BPVC, Section II, Part A.
- Bolting: ASME SA-193 Grade B7 for Class MC components, and ASME SA-193 Grade B8 or SA-437 Grade B4B for containment closure head

3.8.2.6.2 Quality Control

Quality control procedures are established for the Class MC components of the containment, in the construction, fabrication, and installation specifications.

These procedures are in accordance with SRP 3.8.2, RG 1.28, NE-2000, NE-4000, and NE-5000 of ASME BPVC, Section III, Division 1, Subsection NE, NCA-4000 of ASME BPVC, Section III, Subsection NCA, and are developed in compliance with the GEH quality assurance program described in Chapter 17.

3.8.2.6.3 Special Construction Techniques

The Class MC components of the containment do not use special construction techniques.

3.8.2.7 Testing and Inservice Surveillance Requirements

SCCV testing and ISI requirements described in Subsection 3.8.1.7 apply to the Class MC components of the containment. Sufficient physical access is provided in the design to accommodate the ISI of the containment Class MC components.

3.8.3 Containment Internal Structures

The BWRX-300 containment internal structures include the RPV pedestal and the containment internal structural steel. The containment internal structural steel comprises the Containment Equipment and Piping Support Structure (CEPSS) and two support platforms as shown in Figure 3.8-1.

3.8.3.1 Description of Internal Structures

3.8.3.1.1 Reactor Pressure Vessel Pedestal

The RPV pedestal is a cylindrical-shaped structure that supports the RPV. The RPV pedestal is constructed using DP-SC modules and is integrated with the common mat foundation as shown in Figure 3.8-1.

The RPV pedestal is equipped with structural steel that lines the top of the RPV pedestal where the RPV skirt is anchored using anchor bolts. The RPV pedestal also provides structural support for the RPV bottom stabilizers, the CRD housing outer springs, and the CEPSS. The part of the

RPV pedestal surrounding the core region of RPV and the non-structural short concrete wall with steel face plates added on top of it help to attenuate the radiation emanating from the RPV. Openings are provided in the RPV pedestal to permit the routing of necessary piping to the RPV, to permit ISI of the RPV and piping, and to ensure personnel access into the under-vessel region.

3.8.3.1.2 Containment Equipment and Piping Support Structure

The CEPSS is supported vertically by the RPV pedestal and is laterally supported through tangential restraints to the SCCV as shown in Figure 3.8-1. The CEPSS framing connects directly to the RPV pedestal. Shear lug support connections with the SCCV are used to allow free thermal expansion of the CEPSS while resisting CEPSS lateral forces.

The CEPSS consists of various structural components, such as beams and columns, as shown in Figure 3.8-1. The CEPSS framing includes vertical bracing members around the CEPSS outer perimeter (near SCCV wall) and inner perimeter (above the pedestal), and horizontal bracing members to transfer lateral forces to the SCCV wall.

The CEPSS structure supports the RPV top stabilizers that provide horizontal bracing for the RPV. In addition to the RPV stabilizers, the CEPSS also supports piping, RIVs including actuator, and miscellaneous platforms needed for personnel access and equipment inspection and maintenance.

3.8.3.1.3 Support Platforms

The steel support platforms shown in Figure 3.8-1 provide support for miscellaneous components, including fans and coolers associated with the containment cooling system, and for apparatus needed for equipment inspection and maintenance.

The steel support platform beams are supported by the RPV pedestal and SCCV wall as shown in Figure 3.8-1.

3.8.3.2 Applicable Codes, Standards, and Specifications

The design, fabrication, construction, testing, and ISI of the containment internal structures conform to 10 CFR 50 and comply with the provisions of GDC 1, 2, 4, and 50 as discussed in Section 3.1 and explained below.

The analysis, design, fabrication and testing of the DP-SC RPV pedestal is in accordance with ANSI/AISC N690, endorsed and modified by RG 1.243, “Safety-Related Steel Structures and Steel-Plate Composite Walls for Other Than Reactor Vessels and Containments,” including the modified design rules for the BWRX-300 non-containment steel-plate composite structures provided in Section 5.0 of NEDC-33926P (see Section 3.8.4.1.2 for more details). This approach meets the intent of the guidance of SRP 3.8.3, “Concrete and Steel Internal Structures of Steel or Concrete Containments,” and complies with the GDC requirements.

The analysis, design, fabrication and testing of the containment internal structural steel is in accordance with ANSI/AISC N690 consistent with SRP 3.8.3.

The design codes jurisdictional boundary for the RPV pedestal and internal structural steel are provided in Figure 3.8-2.

3.8.3.3 Loads and Loading Combinations

The containment internal structures are completely contained within and integrated with the RB and SCCV. As a result, the design of the containment internal structures considers both design loads applied directly to the containment internal structures and those applied indirectly through the RB and SCCV.

3.8.3.3.1 Design Loads

Refer to Subsections 3.8.1.3 and 3.8.4.1.3 for the description of design loads applicable for the SCCV and RB structures that are also generally applicable for the design of containment internal structures.

The design loads also include the reactions from the RPV at the support locations on the containment internal structures and other bracket and attachment loads applicable during different plant conditions. The RPV lumped mass beam model representing the mass and stiffness properties of the RPV is included in the integrated RB FE model as discussed in Subsection 3.7.2.3.2. Consequently, dead load and seismic load reactions from the RPV are obtained directly from the static and seismic analyses discussed in Subsection 3.8.4.1.4. Other normal and accidental plant operating loads are applied to the model as reaction force loads.

3.8.3.3.2 Load Combinations

Following the guidance of Subsection II.3 of SRP 3.8.3, load combinations and load factors for the design of the steel-plate composite structures and structural steel that form the containment internal structures are in accordance with ANSI/AISC N690, including the supplemental guidance of RG 1.243.

They are covered by the comprehensive set of load combinations listed in Table 3.8-7 used for the design of the RB structure.

3.8.3.4 Design and Analysis Procedures

Analysis and design procedures for the containment internal structures are provided in the following subsections. These procedures meet the guidance provided in Subsection II.4 of SRP 3.8.3. Design demands for critical sections of the containment internal structures are provided in Appendix 3G.

3.8.3.4.1 Reactor Pressure Vessel Pedestal

The RPV pedestal is part of the integrated RB FE model and is analyzed and designed using the same procedures outlined in Subsection 3.8.4.1.4 for the RB.

The RPV pedestal in the integrated RB FE model includes major openings and penetrations in accordance with Appendix N9 of ANSI/AISC N690. The state of stress and behavior of the RPV Pedestal around these openings is determined by use of analytical techniques.

The RPV pedestal supports and transfers vertical and lateral loads from the RPV, CEPSS and support platforms to the SCCV (inner) mat foundation as described in Subsection 3.8.4.1.4. The connections between the RPV pedestal, the RPV and other containment internal structures are appropriately modeled in the integrated RB FE model to reflect the load transfer for the vertical, thermal, reactions forces, and lateral loads discussed in Subsection 3.8.3.3.1.

3.8.3.4.2 Containment Equipment and Piping Support Structure

The CEPSS is part of the integrated RB FE model and is analyzed as discussed in Subsection 3.8.4.1.4.

The CEPSS supports and transfers vertical and lateral loads coming from the containment equipment and piping to the RPV pedestal and SCCV wall as described in Subsection 3.8.4.1.4. The connections between the CEPSS, the RPV pedestal and SCCV are appropriately modeled in the integrated RB FE model to reflect the load transfer for vertical and lateral loads.

The CEPSS is designed in accordance with ANSI/AISC N690 and is designed to carry piping dynamic loads without buckling and while remaining elastic. Pipe whip restraints attached to supporting CEPSS beams and columns are designed with the ability to sustain limited inelastic deformation without rupturing. SC1 SSCs affected by these inelastic deformations are evaluated to verify that their safety functions are not compromised.

3.8.3.4.3 Support Platforms

The support platforms shown in Figure 3.8-1 are part of the integrated RB FE model and are analyzed and designed using the same analytical and design procedures as those for the CEPSS discussed in Subsection 3.8.3.4.2.

The support platforms vertical and lateral loads are supported by the RPV pedestal and SCCV wall as described in Subsection 3.8.4.1.4.

3.8.3.5 Structural Acceptance Criteria

Acceptance criteria for the design of DP-SC RPV Pedestal, including welded and bolted connections, are in accordance with Section 5.0 of NEDC-33926P.

The acceptance criteria for the containment internal structural steel are in accordance with ANSI/AISC N690, including the guidance of SRP 3.8.3 and RG 1.243.

3.8.3.6 Materials, Quality Control, and Special Construction Techniques

3.8.3.6.1 Materials

To enhance shielding, a high-density self-consolidating concrete designed in accordance with RG 1.69 is used in the RPV pedestal DP-SC modules.

The design compressive strength for the pedestal high-density self-consolidating concrete infill is determined as described in Section 5.2.1 of NEDC-33926P. Aggregates used in areas subjected to elevated temperature for long durations are free of pyretic materials.

The RPV pedestal DP-SC steel components conform to the following:

- Steel faceplates/diaphragm plate: ASTM A572 Grade 50 or Grade 65
- Studs: ASTM A108 Type B

The RPV pedestal structural steel components conform to ASTM A572 Grade 50.

Materials used in construction of the containment internal structural steel are in accordance with ANSI/AISC N690.

The containment internal structural steel conforms to:

- Structural steel and connections: ASTM A500, “Standard Specification for Cold-Formed Welded and Seamless Carbon Steel Structural Tubing in Rounds and Shapes,” (Reference 3.8-21) or ASTM A1085, “Standard Specification for Cold-Formed Welded Carbon Steel Hollow Structural Sections,” (Reference 3.8-22)
- High-strength structural steel plates: ASTM A572
- Structural steel attachments to SCCV: ASTM A572 Grade 50 per ASME Code Case N-632

Corrosion protection coatings are applied on the exposed surface of the containment internal structures to protect the metal from corrosion.

3.8.3.6.2 Quality Control

The quality control procedures governing the design, fabrication, construction, installation, and inspection of the RPV pedestal are the same as those for the RB structure described in Subsection 3.8.4.1.6.

The quality control procedures governing the design, fabrication, construction, installation, and inspection of the containment internal structural steel are in accordance with SRP 3.8.3, RG 1.28 and Chapters NM and NN of ANSI/AISC N690. The procedures are developed in compliance with the GEH quality assurance program described in Chapter 17.

3.8.3.6.3 Special Construction Techniques

The RPV pedestal is constructed using modular construction technique as described in Subsection 3.8.4.1.6.

3.8.3.7 Testing and Inservice Surveillance Requirements

A formal program of testing and ISI is not required for the containment internal structures as these structures do not serve any pressure retaining function. However, due to their contribution to the containment structural function, the condition of the containment internal structures is monitored during the operating life of the plant in compliance with 10 CFR 50.65 and in accordance with RG 1.160, “Monitoring the Effectiveness of Maintenance at Nuclear Power Plants.” To accommodate the ISI of containment internal structures, the design provides sufficient physical access to the structures.

3.8.4 Other Seismic Category I Structures

The primary focus of this section is on the RB structure, the only Seismic Category I structure outside of the containment. Other structures discussed in this section include the Radwaste Building (RWB) which processes and houses liquid, solid and gaseous radwaste and the Control Building (CB) locally hardened by design to meet the control room habitability requirements. Level of content provided in the following subsections is commensurate with the safety classification of the structures. For information on other Power Block structures, refer to Section 3.7.

3.8.4.1 Reactor Building

3.8.4.1.1 Description of the Structure

The RB is a deeply embedded cylindrical-shaped building made of steel-plate composite floors and walls, with structural steel members supporting the roof structure. Two types of steel-plate composite modules are used for the construction of the RB structures which have the same overall performance characteristics but different steel ties configuration. DP-SC modules, the steel-plate composite type predominantly used for the construction of the RB structures, rely on diaphragm plates to attach the two faceplates and provide the composite action between the steel faceplates and the concrete core as described in Subsection 3.8.1.1. Conventional steel-plate composite modules use discrete tie bars instead of diaphragm plate to attach the faceplates as described in Section 3.4 of NEDC-33926P.

The below grade portion of the RB structure encloses the containment and protects the RPV, reactor support and SC1 SSCs, and most of vital and non-vital power supplies and equipment. While the majority of the RPV and SCCV is located below grade, the top elevation of the RPV and SCCV top slab are above grade. In addition, the above grade portion of RB structure houses the refueling floor, refueling and fuel handling systems, pools, and polar crane.

The RB fuel pool provides for storage of new and spent fuel, along with the in-core components removed from the RPV during refueling. New fuel is staged in fuel racks located in the fuel pool. An area in the deep pit is used for loading of a spent fuel cask. The fuel racks are Seismic Category I structures and are designed to withstand an SSE without failure of the basic structure or damage to the active region of irradiated fuel. For the performance characteristics, physical arrangement, operation, and design of the fuel racks, refer to Subsection 9.1.2.

The RB polar crane is composed of an overhead bridge of two deep girders supporting a trolley with a main and auxiliary hook. The top of circular rail is attached to the RB exterior wall and the bridge structure spans the full width of the refueling floor. The crane is classified as Seismic Category II to maintain structural integrity and is designed as a single failure proof system to mitigate the probability of a load drop event. For more information on the design of the RB polar crane, refer to Subsection 9.1.5.

Section 1.2 provides key dimensions of the RB, while Figure 3.8-1 presents an elevation sectional view of the structure. Figure 3.8-2 depicts the separation of the RB structure boundary from the containment pressure boundary discussed in Subsection 3.8.1.2. The RB structural boundary includes the following areas:

1. DP-SC mat foundation portion between the SCCV wall and the RB exterior wall
2. RB below grade (from the mat foundation) to the support for the polar crane, including the roof structure
3. Isolation condenser pools, fuel pool, equipment pool, and the reactor cavity pool composed of steel-plate composite walls that are lined for corrosion protection with leakage detection system as applicable
4. Rooms at several elevation levels outside the containment, structurally integral with the containment structure

In addition to sharing the common mat foundation, the RB and SCCV structures are also integrated at the connections of wing walls and elevated slabs between the mat foundation and the reactor cavity pool top slab elevation of the structure as shown in Figure 3.8-1.

The primary functions of the RB are:

1. To house the reactor vessel, the containment structure, the reactor support structure of the reactor coolant system and fuel handling equipment, biological shielding, and associated equipment and structures.
2. To provide adequate space for the operation, maintenance, and removal of equipment housed within the containment structure during periodic maintenance.
3. To provide protection for SC1 SSCs defined in Section 3.2 from environmental and natural hazards phenomena, such as floods, winds, tornadoes, hurricanes, and earthquakes.
4. To provide protection for SC1 SSCs from external (e.g., explosions and missiles from nearby transportation/industry or aircraft impact) and internal (e.g., pipe breaks and heavy load drops) hazards.
5. To support the habitability functions for the Secondary Control Room (SCR) such as radiological shielding and toxic gas isolation and passive cooling for human occupancy in addition to environmental qualification for equipment.

3.8.4.1.2 Applicable Codes, Standards, and Specifications

Codes, standards, specifications, and regulations applicable for the analysis, design, fabrication, construction, testing, and ISI of the RB are listed in NEDC-33926P. Conformance to regulatory requirements and guidance is discussed in Chapter 1, Section 3.1, and Section 2.0 of NEDC-33926P.

To comply with 10 CFR 50 and the provisions of GDC 1, 2 and 4, the materials, analysis, design, fabrication, construction, examination and testing of the RB structural steel and steel-plate composite components are in accordance with ANSI/AISC N690, including the supplemental guidance of RG 1.243 and SRP 3.8.4, “Other Seismic Category I Structures.”

The design of the RB DP-SC walls, slabs and mat foundation also meets the provisions of Section 5.0 of NEDC-33926P. NEDC-33926P, Section 5.0 provisions are adapted from ANSI/AISC N690 and adjusted to address the particularities of DP-SC construction. Sections 5.9 and 5.12 of NEDC-33926P justify why the provisions of Appendix N9 of ANSI/AISC N690 can be extended to the design of the RB DP-SC floors and curved walls. The design approach discussed in Section 5.0 of NEDC-33926P ensures a level of safety and performance for the RB DP-SC structures commensurate to that required by codes and standards listed in Subsection II.2 of SRP 3.8.4.

In addition to meeting the requirements of ANSI/AISC N690 and guidance of RG 1.243, the RB polar crane rail clips, runway girders, and support corbels are also designed to meet the requirements of ASCE/SEI 7-16, “Minimum Design Loads and Associated Criteria for Buildings and Other Structures,” (Reference 3.8-23) and Sections 4160 and 4460 of ASME NOG-1, “Minimum Design Loads and Associated Criteria for Buildings and Other Structures,” (Reference 3.8-24). Crane loading is developed in accordance with Section 4.9 of ASCE/SEI 7-16.

3.8.4.1.3 Loads and Loading Combinations

In addition to the loads applicable directly to the RB, loads considered in the design of the RB include loads applied to the SCCV that are transferred to the RB structural components.

Loads and load combinations considered in the design of the RB meet the intent of Subsection II.3 of SRP 3.8.4.

Design Loads

Loads used in the design of the RB structure are in accordance with ANSI/AISC N690, following the guidance of SRP 3.8.4.

Loads, such as accident pressure and thermal transient loads due to a LOCA internal to SCCV, are also considered for the design of structural components of the RB that are integrated with the SCCV.

RB design loads consist of:

- Service category of loads that occur during construction, pre-operational testing, or normal operation. They include:
  - Dead loads (D) which consist of the weight of structures, weight of permanently attached major equipment, tanks, machinery, and cranes; and weight of piping, cable, cable trays and duct supports
  - Hydrostatic pressure (F) of liquids in various pools
  - Live loads (L, L_r) which consist of floor area loads, laydown loads, nuclear fuel, and equipment handling loads
  - Lateral Soil and groundwater pressure loads (H)
  - Snow/rain loads (S/R)
  - Normal plant operation and pre-operation pressure testing loads which consist of operation service pressure loads, pre-operation proof test pressure load, normal thermal conditions (T_o) and operation service pipe and equipment reaction loads (R_o)
  - Construction Loads
  - Settlement Loads
  - Crane Loads (C) developed as discussed in Subsection 3.8.4.1.2
- Abnormal and environmental category of loads that occur during postulated accidents and/or severe or extreme environmental events. They include:
  - Abnormal plant operation loads which include accident pressure (P_a) and thermal (T_a) loads, accident pipe reaction loads (R_a), high-energy pipe rupture loads (Y_r), missile generation, pipe whip (Y_m), jet impingement from large pipe breaks (Y_j), blast pressure and compartment pressurization
  - Wind and Tornado or Hurricane loads (W, W_t)
  - Seismic loads (E_s) discussed in Subsection 3.7.1, including hydrodynamic loads on the pool walls calculated based on the approach described in ASCE/SEI 4-16, “Seismic Analysis of Safety-Related Nuclear Structures,” (Reference 3.8-25) and American Concrete Institute (ACI) 350.3, “Code Requirements for Seismic Analysis and Design of Liquid-Containing Concrete Structures (ACI 350.3-20) and Commentary,” (Reference 3.8-26), and dynamic lateral pressures from the interaction of the deeply embedded structure with the surrounding rock and soil.

Load Combinations

Load combinations and load factors for the design of the RB steel-plate composite structures and structural steel are in accordance with the provisions of Section NB2.5 of ANSI/AISC N690 including the supplemental guidance of Regulatory Positions 2.1 and 2.2 of RG 1.243.

Table 3.8-7 provides the load combinations and load factors used in the design of the RB.

3.8.4.1.4 Design and Analysis Procedures

Analysis Method

The RB, containment and the containment internal structures are analyzed as one integrated structure, using ANSYS and ACS SASSI computer programs, to determine structural design demands resulting from various design loads and design load combinations. Evidence of qualification of these computer programs, including a description of the programs and extent of use, is presented in Appendix 3I.

Four types of analyses are performed to obtain design demands for the integrated RB structures:

- 1-g static SSI analyses
- Static and quasi-static analyses
- Thermal stress analyses
- Seismic SSI analyses

These analyses are performed on integrated RB structural models that have the same node and element type configurations. The use of linear elastic models with identical FE configuration enables the demands obtained from different analysis cases to be combined on an element-by-element basis for the applicable design load combinations per governing design codes. For more information on the analysis models, analysis cases and model requirements, including boundary conditions considered, refer to Appendices 3B, 3C and 3E.

Integrated RB Finite Element Model

The integrated RB detailed structural model used in the various structural analyses is presented in Section 3B.1. This model is developed following the general FE modeling guidelines discussed in Subsection 3.7.2.3 and Section 5.1.1 of NEDO-33914-A. The model adequately represents the RB structural configuration for all main structural members, including their foundations, penetrations, and openings. The model meets the mesh refinement and quality attributes required for calculation of structural stress demands.

Materials properties assigned to the model depend on the analyzed loads and resulting stress responses. Unit weight properties are assigned to the models used for the 1-g static SSI analyses to adequately simulate gravity and earth pressure loads. Seismic mass inertia properties assigned to the dynamic model used for the seismic SSI analyses are discussed in Subsection 3.7.2.3.

Stiffness properties are assigned to the SCCV and RB to reflect effective stiffness for load combinations without accidental thermal load. For load combinations with accidental thermal load, reduced stiffness is considered to account for the cracking effects on the redistribution of forces and moments. The effective stiffnesses of DP-SC and conventional steel-plate composite structural elements and their connections are computed as discussed in Sections 5.5 and 5.6 of NEDC-33926P.

The effect of interaction with the surrounding subgrade is incorporated in the analyses of the deeply embedded integrated RB by considering the surrounding soil and rock as a layered half-space continuum. Elastic spring elements are used to model the interfaces of the RB and surrounding subgrade. These spring elements provide results that are used to calculate static and dynamic earth pressures. The geotechnical design parameters used as input for the static and thermal analyses are discussed in Subsection 3.8.5.4.1. Dynamic subgrade properties developed for the seismic SSI analyses of the integrated RB are discussed in Subsection 3.7.1.3 and Appendix 3C. Excavation support and backfill effects on the analysis results are evaluated as discussed in Subsection 3.7.2.9.

Integrated Reactor Building Load Path

The load path to foundation for vertical loads within the integrated RB and SCCV structures is as follows:

- Vertical loads from the RB roof slab are transferred to the roof steel beams that are supported by the RB exterior wall
- The refueling floor vertical loads are transferred to the RB exterior wall and pool walls
- Vertical loads on the pools are transferred through the pool slab to the SCCV wall, wing walls, and RB exterior wall
- Vertical loads on the RB floors are primarily transferred to SCCV wall, wing walls, and the RB exterior wall, with some of the vertical loads from the slabs transferred to the elevator and staircase shaft wall
- The crane vertical load is transferred to the crane corbels integrated into the RB exterior wall
- The RPV vertical loads and vertical loads coming from the containment equipment and piping supported by the CEPSS framing are transferred to the RPV pedestal
- Vertical loads from the support platforms inside containment are transferred to the SCCV wall and RPV pedestal
- All vertical loads on the RB exterior wall, wing walls, SCCV wall, and the RPV pedestal are transferred to the common mat foundation

The load path to foundation for lateral loads is as follows:

- The RB roof lateral loads are transferred through the roof diaphragm to the RB exterior wall
- The refueling floor lateral loads are transferred to the RB exterior wall and pool walls
- The hydrostatic and hydrodynamic fluid loads in pools are transferred to the pool walls which then transfer the loads to the slabs above or below
- Lateral loads on the RB floors are transferred to the SCCV wall, wing walls, and the RB exterior wall which, in turn transfer the loads to the common mat foundation
- The crane lateral load transverse to the crane girder is transferred to the crane corbels at both ends. The crane lateral load parallel to the crane girder is transferred to one side of the crane corbel.

- The RPV lateral load is transferred tangentially only through the top stabilizers at the top to the CEPSS, the bottom stabilizers at mid-height of the RPV pedestal, and through the RPV skirt to the top of the pedestal. The transfer of only tangential shear at the stabilizers is to allow RPV vertical and radial thermal expansion relative to the skirt while still providing lateral and rotational rigidity and load transfer.
- Lateral loads from the containment equipment and piping are transferred through the CEPSS framing to the RPV pedestal and SCCV wall. The CEPSS framing transfers lateral loads to the SCCV through tangential only supports to allow the vertical and radial relative expansion between the CEPSS and SCCV.
- Lateral loads from the RPV pedestal are primarily transferred to the SCCV (inner) mat foundation, with some of the loads being transferred through the CEPSS
- The SCCV wall and RPV pedestal transfer lateral load from the support platforms inside containment to the inner mat foundation
- The static and dynamic lateral earth pressures are mainly resisted by the below grade portion of the RB cylindrical exterior wall. Due to the Integrated RB design, some portions of these pressures are transferred indirectly to the SCCV through the wing walls and floors.

1-g Static SSI Analyses

The 1-g static SSI analyses provide demands from the Earth gravity (1-g) loads due to:

- The dead load (D) from the weight of the RB structure and equipment
- The vertical fluid loads (F) from the hydrostatic pressure on the pool slabs
- The static lateral earth pressure load (H) on the below grade RB exterior wall including surcharge lateral pressures loads applied from the surrounding power block buildings and foundations, excluding groundwater loads

The 1-g static SSI analyses utilize a model including all power block buildings with the subgrade. Lower Bound (LB) equivalent linear stiffness properties and Upper Bound (UB) unit weight properties assigned to the subgrade model used in the 1-g static SSI analyses are discussed in Subsection 3.8.5.4.1.

Stress demands obtained from the one-step 1-g static SSI analyses include the effects of static earth pressures simulated by the interaction of the integrated RB structural model with the subgrade FE model. The applicable overburden inertia loads from the surrounding Power Block foundations and other surcharge loads are included in the 1-g analysis since models of the Power Block buildings and foundations are explicitly included in the 1-g static SSI model.

Following the guidance of Section 5.1.2 of NEDO-33914-A, the following stiffness properties are assigned to the contact springs in the models used for the 1-g static SSI analyses to provide UB lateral soil pressures on the RB below grade exterior wall:

- The contact springs in the direction normal to the RB exterior walls are assigned properties representing UB stiffness conditions at the SSI interfaces.

- The friction at the RB exterior walls is not considered by assigning very low stiffness properties to the contact springs in vertical and tangential direction.

Subgrade Modeling Assumptions for Deeply embedded RB

In accordance with Section 5.1.2 of NEDO-33914-A, the following assumptions related to the modeling of the subgrade are introduced in the 1-g static SSI analyses. These assumptions enable an efficient calculation of stress demands on the RB structure due to pressure loads from soil and rock surrounding and supporting the RB shaft:

1. The properties of the subgrade materials are represented by linear elastic constitutive models.

2. The non-linearities at soil-structure interfaces are not considered.

3. The rock mass is assumed continuous and the presence of cavities, fracture zones, joints, bedding planes, discontinuities and other weak zones is not considered.

The soil and rock strata in the 1-g static SSI models are modeled based on the principles of continuum mechanics using isotropic linear elastic properties. Possible fracture zones, joints, bedding planes, discontinuities and cavities in the rock are not explicitly included in the design SSI analyses models. Static properties assigned to the soil and rock materials are discussed in Subsection 3.8.5.4.1. Stiffness properties assigned to contact springs at the interface of the RB and the surrounding subgrade follow the guidelines of Section 5.1.2 of NEDO-33914-A.

Rock with disadvantageous fracture zones, joints, bedding planes and discontinuities is reinforced to create a more self-supporting rock mass. If needed, rock reinforcements are provided as initial ground support. The rock reinforcements and other supports provided during the excavation and construction may degrade and are inaccessible after construction. Therefore, the design addresses the rock loads remaining after the initial ground support degrades by including the potential weight of the rock in the static 1-g SSI analysis or by applying additional pressures on the RB exterior wall.

RB Design Earth Pressure Load Validation

Validations of the earth pressure loads are to be performed following the guidelines in Section 5.1.3 of NEDO-33914-A to ensure the 1-g SSI static analysis provides conservative earth pressure design demands on the deeply embedded RB structure.

Following the guidance of Section 4 of NEDO-33914-A, Foundation Interface Analysis (FIA) is performed as described in Chapter 2, on models capturing the non-linear constitutive behavior of soil and rock materials surrounding the RB shaft. These models employ non-linear interface modeling features capable of capturing the effects of non-linearities at the subgrade structure contact surfaces. The results of the FIA are to be used for validation of the design earth pressures following the guidance of Section 5.1.3 of NEDO-33914-A.

Static and Quasi-Static Analyses

The static and quasi-static analyses provide stress demands due to:

- Live loads
- Crane loads
- SIT and accident condition containment internal pressure load including differential containment and RB sub-compartment loads
- Horizontal hydrostatic pressure loads on pool walls
- Groundwater pressure loads on the integrated RB mat foundation and below-ground exterior wall
- Extreme wind loads on RB roof and exterior wall
- Rain and snow loads
- Seismic water sloshing and breathing mode quasi-static pressure loads on pool walls
- Quasi-static pressure loads due to high-energy line break (jet impingement, blast loads)
- Equipment and pipe reaction loads including RPV reaction loads
- Post-accident internal flooding loads

The analyses of global static and quasi-static loads that can affect the global response of the integrated RB consider the effect of subgrade stiffness. Following the sub-structuring methodology, design demands from these loads are obtained from subgrade stiffness impedance analyses performed on models consisting of two parts:

- Super-element representing LB stiffness of the subgrade surrounding the RB
- Integrated FE model of the RB, containment, and containment internal structures

The super-elements define the stiffness of the subgrade at the nodes of the RB interfaces with the surrounding soil. The stiffness properties of the super-elements are developed using a layered 3D solid FE model. Subgrade stiffness properties assigned to the super-elements are described in Subsection 3.8.5.4.1. To adequately simulate half-space boundary conditions, the depth of these models is deeper than three times the largest foundation dimension, or two times the depth of the RB embedment. The horizontal extent of these models is more than three times the RB shaft diameter.

The nodes of the super-element are coincident with the nodes of the integrated RB FE structural model. The coincident super-element and structural model nodes are connected by contact spring elements. LB stiffness properties are assigned to these contact spring elements to yield larger structural deformations and conservative design stress demands.

Fixed bases analyses are performed for the local loads with smaller magnitudes that do not affect the Integrated RB mat foundation or global response.

Demands due to hydrostatic lateral pressure loads are obtained from static analyses of the integrated RB model with vertical supports applied to all mat foundation nodes. Demands from the upward buoyant pressures on the mat foundation are obtained from a static analysis of the

integrated RB structural model with vertical supports at the nodes connecting the RB exterior wall with the mat foundation and horizontal supports established at the central node of the mat. The results from the two groundwater load analyses are combined with the results of the 1-g SSI analysis cases to obtain earth pressure and groundwater load demands for the design of integrated RB structure.

Thermal Stress Analyses

The structural stress demands caused by component temperatures resulting from normal operating conditions and DBA events are calculated from analyses of the integrated RB FE structural model including the subgrade super-element.

Equivalent stiffness properties are assigned to the steel-plate composite shell elements to account for the stiffness reduction effects under normal operating and DBA temperatures.

Static subgrade properties representing both UB and LB stiffness are considered for the super-element modeling the subgrade. The variation of subgrade modeling representing UB and LB properties is considered and enveloped in order to develop conservative thermal internal force demands for the design of the RB and containment structures. Equivalent linear subgrade stiffness properties assigned for the thermal stress analyses are discussed in Subsection 3.8.5.4.1.

Seismic SSI Analyses

Design internal force effects caused by SSE seismic demands and dynamic subgrade pressures are obtained directly from the results of the SSI seismic analyses performed using the one-step approach discussed in Subsection 3.7.2.1. Dynamic subgrade properties used as input in the seismic SSI analysis are discussed in Subsection 3.7.1.3 and Appendix 3C.

Design Method

The design of the RB DP-SC structures conforms to the requirements of Section 5.0 of NEDC-33926P and meets the acceptance criteria discussed in Subsection 3.8.4.1.5. Conventional steel-plate composite structures are designed per the requirements of ANSI/AISC N690 as supplemented by RG 1.243. Steel-plate composite connections in the RB are designed per the requirements of Section 5.11 of NEDC-33926P and are further discussed in Appendix 3B and Appendix 3H. The design of the RB steel structures is per ANSI/AISC N690 and meets the acceptance criteria discussed in Subsection 3.8.4.1.5.

Membrane forces, shear forces and bending moments used in the design of the RB structure are obtained from the linear elastic SSI analyses for the integrated RB FE model for the loads and load combinations defined in Subsection 3.8.4.1.3.

Results from the FE analyses are evaluated to identify critical cross-sections where maximum structural demands occur for different controlling loads and load combinations. Key responses reviewed include:

- Vertical bending moment demands on the RB outer shaft and SCCV wall, at base of walls and at cross sections near the plant grade elevation
- Out-of-plane bending demands for major floor slabs and the RB foundation mat at mid-span and near the slab supports
- In-plane shear demands on major interior walls
- Bending moment demands on roof girders

Appendix 3H presents design demands for critical RB sections identified per the criteria above. The structural demands at the critical locations are used to evaluate the design of the critical cross-sections and connections using the applicable codes of record.

The integrated RB curved walls are designed and detailed to have a radius-to-wall panel thickness greater than 2.0 which minimizes the effects of curvature on the section behavior, as discussed in Section 5.12 of NEDC-33926P. The steel faceplates of DP-SC modules are designed to be non-slender as referenced in Section 5.3 of NEDC-33926P. As a result, the faceplates can accommodate the residual stress distribution due to rolling of materials during fabrication of curved sections without compromising their membrane stress capacity in both tensions and compression. Any residual stresses and strains resulting from rolling of the curved plates are evaluated and incorporated into detailed design.

3.8.4.1.5 Structural Acceptance Criteria

For a comparison of the calculated stresses and strains in key RB structural components with the allowable limits, refer to the analysis results in Appendix 3H.

Design Basis Acceptance Criteria

The RB steel-plate composite and steel structures, including welded and bolted connections, are designed to meet the acceptance criteria outlined in ANSI/AISC N690 and in Section 5.0 of NEDC-33926P.

The RB structure is evaluated for serviceability considerations including deflection, vibration, permanent deformation, cracking, and settlement. Serviceability evaluations meet the acceptance criteria in Chapter NL of ANSI/AISC N690.

Seismic Design Criteria

In accordance with Table 3.7-1, the seismic design of the RB structure considers LS-D response in accordance with ASCE/SEI 43-19 to ensure an essentially elastic response without any significant permanent deformations when subjected to SSE and meets the deformation acceptance criteria of Section 5.2.3 of ASCE/SEI 43-19.

Interaction Evaluation Criteria

The interaction of the RB structure with the adjacent Power Block structures is discussed in Subsections 3.3.2.3 and 3.7.2.8.

The stability of foundations under SSE and extreme wind loads are checked following the criteria in Subsection 3.8.5.4.3.

Design for Impulsive and Impactive Loads

The RB structure is designed for impulsive and impactive loads per the guidance of SRP 3.8.4.

The RB is designed to withstand intrusion by regulatory defined threats by selecting design parameters for the steel-plate composite modules, such as steel thickness, steel ductility, and concrete thickness. The RB design for impulsive and impactive loads follows the provisions of ANSI/AISC N690 and the relevant guidance of RG 1.243. Allowable stresses and limits for the RB design for impulsive and impactive loads are provided in Section 5.8 of NEDC-33926P.

3.8.4.1.6 Material, Quality Control and Special Construction Techniques

Material

Materials used in construction of the RB steel-plate composite structures outside of containment are in accordance with Section 5.2 of NEDC-33926P and Section NA3 of ANSI/AISC N690.

RB structural steel materials conform with the guidance of SRP 3.8.4.

The NRIC Demonstration Program Prototype test conclusions are used for demonstrating the structural performance of DP-SC modules and the adequacy of the proposed material requirements and design approaches discussed in Sections 5.0 of NEDC-33926P.

The following are the properties of materials used in the construction of the RB:

Concrete Infill

The design compressive strength for the self-consolidating concrete used for the construction of the RB is determined as described in Section 5.2.1 of NEDC-33926P.

Concrete constituents used in the RB steel-plate composite modules are tested, batched, and mixed in accordance with ACI 349-13, “Code Requirements for Nuclear Safety-Related Concrete Structures and Commentary,” (Reference 3.8-27).

High-density concrete used for shielding purposes is designed in accordance with RG 1.69. Aggregates used in high-density concrete for radiation shielding purposes conform to ASTM C637, “Standard Specification for Aggregates for Radiation-Shielding Concrete,” (Reference 3.8-28) per ACI 349-13.

Steel Materials

The steel components of the RB steel-plate composite structures conform to the following:

- Steel faceplates/diaphragm plate: ASTM A572 Grade 50 or Grade 65
- Studs: ASTM A108 Type B

The RB structural steel components conform to ASTM A572 Grade 50 or Grade 65.

Steel Connections

Bolts used in structural steel bolted connections are ASTM F3125 Grade A325 Type 1, “Standard Specification for High-Strength Structural Bolts and Assemblies, Steel and Alloy-Steel, Heat Treated, Inch Dimensions 120 ksi and 150 ksi Minimum Tensile Strength, and Metric Dimensions 830 MPA and 1040 MPa Minimum Tensile Strength,” (Reference 3.8-29).

Bolts of the following grades may be used otherwise, when deemed necessary:

- ASTM F3125 Grade A490 Type 1
- ASTM A354 Grade BD, “Standard Specification for Quenched and Tempered Alloy-Steel Bolts, Studs, and Other Externally Threaded Fasteners,” (Reference 3.8-30)
- ASTM A449 Type 1, “Standard Specification for Hex Cap Screws, Bolts and Studs, Steel, Heat Treated, 120/105/90 ksi Minimum Tensile Strength, General Use,” (Reference 3.8-31)
- ASTM A193, “Standard Specification for Alloy-Steel and Stainless-Steel Bolting for High-Temperature or High-Pressure Service and Other Special Purpose Applications,” (Reference 3.8-32) for high service temperature applications, grade is subject to specific design requirements

Welding Materials

Welding materials for the RB structure comply with the requirements of ANSI/AISC N690.

Pool Liners and Appurtenances

Construction, fabrication, and installation of metallic liners, non-metallic liners, coatings, joint sealants, and waterstops for structures where leak tightness is critical meet the guidance of SRP 9.1.2, “New and Spent Fuel Storage.”

Pool liners are selected to withstand the environmental conditions they are to encounter during the life of the facility. Pool liners, and their connections, are designed to sustain high-temperatures, resist radiation exposure, resist impactive and abrasive loads, maintain leak tightness and maintain the pool inventory at acceptable levels during and after normal operating and design basis events. Pool liner materials or coatings are also designed to resist flaking or chipping.

Liner plates may be of the following type and grade:

- Carbon steel with stainless clad:
  - ASTM A264, “Standard Specification for Stainless Chromium-Nickel Steel-Clad Plate,” (Reference 3.8-33)
  - ASTM A516 Grade 70, “Standard Specification for Pressure Vessel Plates, Carbon Steel, for Moderate- and Lower-Temperature Service,” (Reference 3.8-34)
  - ASTM A240 Type 304L, “Standard Specification for Chromium and Chromium-Nickel Stainless-Steel Plate, Sheet, and Strip for Pressure Vessels and for General Application,” (Reference 3.8-35)
- Stainless steel: ASTM A240 Type 304L

Coatings and Other Corrosion Prevention

Corrosion protection measures used for the RB steel faceplates and structural steel are the same as those for the SCCV discussed in Subsection 3.8.1.4.8.

A sacrificial thickness is added to the below grade portion of the RB exterior wall and to the common mat foundation to protect them against corrosion. The calculation of this sacrificial thickness is based on a conservative corrosion rate and the selection of a concrete mix with chemistry control. As stated in Subsection 3.8.1.4.8, the additional sacrificial thickness for corrosion tolerance is not considered in the below grade DP-SC modules strength or stiffness estimates.

Quality Control

Quality control procedures are established and implemented during the construction and inspection phases of the RB. These procedures cover the fabrication, furnishing, and installation of each structural item and specify the inspection and documentation requirements in accordance with the requirements in Section NA5 and Chapters NM and NN of ANSI/AISC N690, RG 1.28 as required by RG 1.243, and as discussed in Sections 5.16 and 5.17 of NEDC-33926P.

The quality control procedures governing the design, fabrication, construction, installation, and inspection of the RB are developed in compliance with the GEH quality assurance program described in Chapter 17.

Special Construction Techniques

The integrated RB is built using a modular construction technique using predominantly DP-SC modules. The fabrication and construction of the RB follow the requirements of Section 5.16 of NEDC-33926P.

3.8.4.1.7 Testing and Inservice Surveillance Requirements

Periodic inspection, and inservice monitoring programs are implemented to ensure the RB structure continues to meet its functional and performance requirements in compliance with 10 CFR 50.65 and following the guidance of RG 1.160.

The aging management, ISI and testing of the RB steel-plate composite structures, in accessible and inaccessible areas, are performed as discussed in Section 5.18 of NEDC-33926P. Inspections and monitoring during construction and commissioning are performed as described in Section 3.2 of NEDO-33914-A. The post-construction testing and inservice surveillance programs for the RB below grade wall and foundation include monitoring of groundwater chemistry, settlements and differential displacements as discussed in Sections 3.3 and 3.4 of NEDO-33914-A.

3.8.4.2 Intervening Structural Elements Between Distribution Systems and Structures

Cable trays, conduits and heating, ventilation, and air conditioning ducts are supported at intervals by appropriately designed supports. The supports are attached to the walls, floors, and ceilings of structures as required by the arrangement. The type of support and spacing considered is determined by systems allowable spans which are governed by rigidity and stress. Bracing is provided where required.

Intervening structural elements between the distribution systems and equipment supports and the building structural elements are accounted for in the design of the structure. The intervening structural elements are designed to withstand the effects of seismic and dynamic loads to prevent the collapse and collision of distribution systems with Seismic Category I SSCs in accordance with the requirements of GDC 2 and 4 and the guidance of SRP 3.8.4. The seismic qualification of the intervening structural elements and their interaction evaluations are performed as discussed in Subsection 3.7.3.

The design of embedded load bearing steel materials in concrete structures will conform to the guidance of RG 1.199, “Anchoring Components and Structural Supports in Concrete.”

3.8.4.3 Radwaste Building

3.8.4.3.1 Description of the Structure

The RWB houses process systems such as the Liquid Waste Management System, the Solid Waste Management System and a portion of the Offgas System including the charcoal adsorbers.

For the RWB location and general dimensions, refer to Section 1.2.

The RWB structure consists of a reinforced concrete exterior wall system with reinforced concrete floor slabs and interior columns resting on a shallow reinforced concrete mat foundation supported by drilled shafts. The RWB roof structure consists of a reinforced concrete deck on open web steel joists supported by steel columns. The lateral force resisting system of the structure consists of reinforced concrete shear walls supporting the reinforced concrete diaphragms at each floor/roof level. Interior reinforced concrete walls are provided for radiological shielding of the liquid and solid management systems and the Offgas System charcoal adsorbers.

Because of its main function which consists of processing and housing liquid, solid and gaseous radioactive wastes, the RWB is categorized as a RW-IIa structure per RG 1.143, “Design Guidance for Radioactive Waste Management Systems, Structures, and Components Installed in Light-Water-Cooled Nuclear Power Plants.” The RWB is also evaluated for interaction with the integrated RB under seismic and extreme wind loadings due to its proximity to the RB as discussed in Sections 3.3 and 3.7. A structural gap is maintained between the RB and RWB to prevent physical contact between the buildings during a seismic or extreme wind event.

3.8.4.3.2 Applicable Codes, Standards, and Specifications

The design, fabrication, construction, testing, and ISI of the RWB conforms to 10 CFR 50 and complies with the provisions of GDC 1, 2, and 4.

The RWB is designed in accordance with RG 1.143, which establishes the appropriate 10 CFR 50 requirements, following the guidance of SRP 3.8.4. Analysis procedures for the RWB are in accordance with ASCE/SEI 4-16 and ASCE/SEI 43-19. Seismic interaction evaluation of the RWB follows the requirements in Subsection 3.7.2.8.

3.8.4.3.3 Loads and Loading Combinations

In accordance with the guidance of SRP 3.8.4, loads and load combinations used in the design of the RWB are in accordance with RG 1.143, Tables 2, 3 and 4.

3.8.4.3.4 Design and Analysis Procedures

The RWB forms part of the combined model used to evaluate the Structure-Soil-Structure Interaction (SSSI) effects of the surrounding Power Block structures on the integrated RB as described in Subsection 3.7.2.4.

The design and seismic interaction evaluation of the RWB structure are performed following the linear elastic analysis methodology using a standalone FE model with a sufficient level of refinement to allow for the accurate estimation of design stresses and forces. The ASCE/SEI 4-16 two-step analysis approach is used for the seismic qualification of the RWB structure. Using this method, seismic demands in the form of RWB zero period accelerations or foundation acceleration response spectra are developed from the RB SSI analyses for the RWB simplified dynamic model discussed in Subsection 3.7.2.3. A fixed base quasi-static analysis using the maximum nodal accelerations or response spectrum analysis using the input foundation response spectrum enveloped with the RWB design earthquake (1/2 SSE) is then performed on the standalone refined FE model of the RWB. Resulting forces and stresses are used for the seismic design of the RWB. The demands for the RWB foundation design are taken directly from the SSI analysis of the integrated RB with the surrounding Power Block structures, with input corresponding to the RWB design earthquake.

The RWB interaction and structural integrity evaluations are performed for SSE loads using the results of the seismic SSI analysis discussed in Subsection 3.7.2.1 and for extreme wind loads. Seismic interaction evaluation of the RWB follows the requirements in Subsection 3.7.2.8. As mentioned in Subsection 3.7.2.8, a gap is maintained between the RB and the RWB to prevent physical contact during a seismic or extreme wind event.

The RWB design follows the guidance of SRP 3.8.4 and RG 1.143. Design and detailing of the RWB structural steel is in accordance with ANSI/AISC N690 as supplemented by RG 1.243. Design and detailing of the RWB structural concrete is in accordance with ACI 349-13, as supplemented by RG 1.142, “Safety-Related Concrete Structures for Nuclear Power Plants (Other than Reactor Vessels and Containments).”

3.8.4.3.5 Structural Acceptance Criteria

The RWB structure is designed to meet the acceptance criteria outlined in ANSI/AISC N690 as endorsed and modified by RG 1.243, and ACI 349-13 as endorsed and modified by RG 1.142, following the guidance of SRP 3.8.4.

3.8.4.3.6 Material, Quality Control and Special Construction Techniques

Materials used in the construction of the RWB are in accordance with ACI 349-13 and ANSI/AISC N690, following the guidance of SRP 3.8.4 and RG 1.143.

The RWB quality control procedures meet the guidance of RG 1.26, “Quality Group Classifications and Standards for Water-, Steam-, and Radioactive-Waste-Containing Components of Nuclear Power Plants,” RG 1.143, Position 7, and ANSI/ANS-55.6, “Liquid Radioactive Waste Processing System for Light-Water Reactor Plants,” (Reference 3.8-36).

The quality control procedures governing the design, fabrication, construction, installation, and inspection of the RWB are developed in compliance with the GEH quality assurance program described in Chapter 17.

The RWB does not use special construction techniques.

3.8.4.3.7 Testing and Inservice Surveillance Requirements

Refer to Chapter 11 for the testing and inservice requirements for process systems inside the RWB.

3.8.4.4 Augmented Power Block Structures

3.8.4.4.1 Control Building

The CB houses the Main Control Room (MCR) and electrical, control and instrumentation equipment. The CB also houses the egress route between the MCR and SCR, which is located in the RB. For the CB location and general dimensions, refer to Section 1.2.

The CB structure consists of reinforced concrete walls with steel columns, beams/girders and composite floors made of concrete and steel decking. The CB is founded on a near surface reinforced concrete mat foundation supported by drilled shafts.

As indicated in Table 3A-2 and Section 3.7, the CB is a Seismic Category II structure designed per the International Building Code (IBC), (Reference 3.8-37) and evaluated for seismic and extreme wind interaction with the integrated RB due to its close proximity to the RB structure. The CB interaction evaluation is performed following the approach in Section 6 of NEDO-33914-A, as discussed in Sections 3.3 and 3.7.

To meet the habitability and safety requirements for the MCR occupants, the MCR and MCR to SCR egress route are also assigned a Seismic Category II and evaluated for a full SSE, considering limited permanent deformation (LS-C), and extreme wind loading per Section 6 of NEDO-33914-A.

Following the guidance of Section 6.0 of NEDO-33914-A and meeting the guidance in Subsection II.2 of SRP 3.7.2 and RG 1.29, “Seismic Design Classification for Nuclear Power Plants,” the CB, MCR and egress route between the MCR and SCR, are designed to maintain their structural integrity under an SSE or extreme wind event to:

- Prevent adverse interaction with the RB Seismic Category I SSCs
- Prevent incapacitating injury to MCR occupants
- Ensure safe egress of MCR occupants to the SCR in the RB

In addition to withstanding the SSE and extreme wind conditions, the MCR and MCR to SCR egress route are hardened by design against perforations by extreme wind missiles as directed by RG 1.117, “Protection Against Extreme Wind Events and Missiles for Nuclear Power Plants.”

The MCR is also designed to meet the bullet resistant requirements of 10 CFR 73.55(e)(5). MCR doors are designed to remain functional and able to open during and after the design basis extreme environmental event.

Unobstructed access of the egress route during and after the events which can initiate an evacuation of the MCR is also ensured by the design to secure the egress of MCR occupants to the SCR.

3.8.5 Foundations

This section presents general design rules for the DP-SC mat foundation supporting the integrated RB. Adjacent Power Block structures’ foundations are also discussed in this section due to their importance to the stability and structural integrity of the integrated RB.

3.8.5.1 Description of the Foundations

3.8.5.1.1 RB and Containment Common Mat Foundation

The integrated RB structure is founded on a circular mat foundation that supports the containment, containment internal structures and RB. The mat foundation is made of DP-SC modules and is deeply embedded in the rock. The mat foundation is a Seismic Category I structure, same as the superstructures it supports. Figure 3.8-8 provides a plan view of the mat foundation, while Figure 3.8-1 provides an elevation sectional view of the foundation. Foundation dimensions and embedment depth are provided in Figure 3.8-8. As stated in Subsection 3.8.1.2.1 and shown in Figure 3.8-2 and Figure 3.8-8, the containment boundary for the mat foundation extends to the outer perimeter of the SCCV referred to as the inner mat foundation. The mat foundation portion outside of the containment boundary is referred to as the outer mat foundation.

3.8.5.1.2 Other Power Block Foundations

The RWB, CB, Turbine Building (TB), Service Building and Reactor Auxiliary structures are supported near the ground surface by drilled shaft deep foundations. The foundations are separated from the RB exterior wall with a gap that can accommodate structural displacements due to seismic and wind loads.

The Power Block structures' foundations are assigned the same seismic category as the superstructures they support. The analysis and design of the Seismic Category RW-IIa RWB foundation is in accordance with ACI 349-13. Structural design and analysis of CB, TB, Service Building and Reactor Auxiliary structures foundations are in accordance with the IBC and ACI 318-22, "Building Code Requirements for Structural Concrete and Commentary," (Reference 3.8-38).

Subsection 2.5.4.10.1 provides the bearing capacity of the in-situ soil materials supporting the Power Block foundations. Stability evaluations of the Power Block structures' foundations against sliding and overturning due to SSE, and extreme wind, and against flotation due to flooding, are performed to ensure the stability requirements under normal operating and accidental conditions discussed in Subsection 3.8.5.4.3 are met. Stability evaluations are performed using the results of the seismic SSI analyses discussed in Subsections 3.7.2 and 3.8.4.1.4. The liquefaction potential of the Power Block structures' foundations is assessed in Subsection 2.5.4.8

Groundwater effects on the Power Block structures' foundations are discussed in Subsections 2.5.4.10 and 2.5.4.13.

3.8.5.2 Applicable Codes, Standards, and Specifications

Applicable codes, standards and specifications for the containment and RB common mat foundation are the same as those for the superstructures discussed in Subsections 3.8.1.2 and 3.8.4.1.2.

The jurisdictional boundary for the application of the NEDC-33926P to the containment mat foundation is the portion within the outer perimeter of the SCCV referred to as the inner mat foundation (see Figure 3.8-2).

The jurisdictional boundary for application of the ANSI/AISC N690 to the non-pressure retaining portion of the mat foundation is the portion spanning from the exterior surface of the SCCV to the exterior surface of the RB referred to as the outer mat foundation.

3.8.5.3 Loads and Load Combinations

Design loads and load combinations for the containment and RB common mat foundation are those of the superstructures described in Subsections 3.8.1.3 and 3.8.4.1.3.

For foundation stability against flotation, the site-specific design basis flood is considered in combination with the dead load in accordance with SRP 3.8.5, “Foundations.”

3.8.5.4 Design and Analysis Procedures

The design and analysis procedures for the DP-SC common mat foundation conform to the guidance in Subsection II.4 of SRP 3.8.5.

As outlined in Subsection 3.8.4.1.4, the common mat foundation supports the integrated RB structures and provides the mechanism for transferring all applicable loads from the integrated RB to the surrounding subgrade.

The mat foundation is analyzed using the methods where the transfer of loads from the foundation mat to the supporting foundation media is determined by elastic methods. Demands for the design of the mat foundation are obtained from the structural analyses described in Subsection 3.8.4.1.4. These analyses are performed on the integrated RB structural model that include the effects of interaction of the structure with the surrounding subgrade and consider the surcharge loads from the foundations of the surrounding Power Block buildings as discussed in Subsection 3.8.4.1.4. Subgrade modeling assumptions used in the analyses are also discussed in Subsection 3.8.4.1.4.

The DP-SC mat foundation is represented by thick shell elements in the integrated RB FE model. Properties assigned to the foundation shell elements in the dynamic FE model used for the seismic SSI analyses are discussed in Subsection 3.7.2.3.1. Properties assigned to the foundation shell elements in the integrated RB FE models used for the static and thermal stress analyses are discussed in Subsection 3.8.4.1.4. Subgrade properties used for the seismic SSI analysis of the mat foundation are discussed in Subsection 3.7.1.3 and Appendix 3C. Subgrade properties used for the static and thermal stress analyses of the mat foundation are discussed in Subsection 3.8.5.4.1.

As stated in Subsection 3.8.4.1.4, elastic springs are used to represent the stiffness properties of the foundation-subgrade interface. Vertical spring force results obtained from these spring elements serve for calculations of foundation bearing stresses. Methodology used to validate the subgrade pressure loads on the common mat foundation is described in Section 5.1.3 of NEDO-33914-A.

The containment (inner) mat foundation is designed in accordance with Section 6.0 of NEDC-33926P, consistent with RG 1.136. The non-pressure retaining portion of the common mat foundation (outer mat foundation) is designed to ANSI/AISC N690, supplemented by RG 1.243 and Section 5.0 of NEDC-33926P.

Allowable bearing capacities for the common mat foundation are addressed in Subsection 3.8.5.4.2. Foundation stability evaluations are performed using the criteria in Subsection 3.8.5.4.3 and results from the FIA discussed in Subsection 2.5.4.13.

3.8.5.4.1 Equivalent Linear Subgrade Static Properties

The structural design demands due to static earth pressures on the RB below grade exterior walls are obtained from the 1-g static analyses of the integrated RB FE model embedded in a layered half-space continuum model representing the surrounding soil and rock. To account for the interaction of the RB integrated structures with the surrounding subgrade, super-elements representing the stiffness properties of the layered subgrade materials are used in the static and thermal analyses, as described in Subsection 3.8.4.1.4.

The 1-g static SSI analyses, subgrade impedance analyses and thermal stress analyses use profiles of equivalent linear soil and rock properties developed using information from the existing CRN site investigation and subsurface material testing programs summarized in Subsection 2.5.4. These properties are developed following Section 5.2.1 of NEDO-33914-A. The properties consist of:

- Effective unit weight that for soil materials below groundwater table are calculated as the total saturated unit weight of soil minus the unit weight of water
- Elastic and shear Modulus representing linearized stiffness properties of the soil and rock for long-term static loading conditions
- Soil and rock Poisson’s ratios are representative of at-rest lateral pressure conditions

Two stratigraphy profiles are developed to bound the geotechnical conditions across the CRN site:

- Profile A uses the lower-range estimate of the one-dimensional stratigraphy for the CRN site. This profile considers a thicker layer of existing fill and residual soil and no weathered rock above the un-weathered rock. Profile A represents a bounding lower subgrade stiffness condition where the thickness of the new fill, and existing fill/residual soils, and the depth to the un-weathered rock are maximized. This subgrade stratigraphy is considered for the analysis load cases with LB subgrades as described in Subsection 3.8.4.1.4.

- Profile B uses the upper-range estimate of the one-dimensional stratigraphy for the CRN site. This profile considers a thinner layer of weathered rock above the un-weathered rock. Profile B represents a bounding upper subgrade stiffness condition where the existing fill/residual soils are not present, weathered rock is present directly beneath the new fill, and the depth to the un-weathered rock is minimized. This subgrade stratigraphy is considered for the analysis load cases with UB subgrades as described in Subsection 3.8.4.1.4.

The equivalent linear subgrade static profiles reflect anticipated as-built conditions at the site after construction of the BWRX-300 small modular reactor and include an appropriate level of conservatism to ensure the design bounds possible changes in site parameters.

The groundwater level considered in the development of the equivalent linear subgrade static properties is discussed in Subsection 3.7.1.3.

Table 3.8-8 provides a summary of the linearized static properties for the 1-g SSI and impedance analyses for internal mechanical loads. Static properties for the thermal stress analysis are provided in Table 3.8-9.

In accordance with the guidance of Section 5.2.1.1 of NEDO 33914-A, the soil Poisson ratios (υ_{st}) are calculated as follows using the at-rest lateral (k_0) coefficient values provided in Table 3.8-8 and Table 3.8-9:

$$\upsilon_{st} = \frac{K_0}{1 + K_0}$$

The UB unit weight, LB static elastic modulus (E_{st}) and UB coefficient of at-rest pressure (K_0) are used for the 1-g SSI analyses resulting in larger deformation at soil-structure interfaces and conservative design stress demands.

3.8.5.4.2 Soil Bearing Stability of Integrated RB Mat Foundation

The static and dynamic stability of soil supporting the integrated RB mat foundation is evaluated in Subsection 2.5.4.10 per the guidance of SRP 2.5.4, “Stability of Subsurface Materials and Foundations.”

The bearing capacity of the rock supporting the integrated RB mat foundation at the CRN site is provided in Subsection 2.5.4.10.1.

The dynamic bearing pressure demands under SSE loads are calculated from the results of the seismic SSI analyses as described in Subsection 3.7.2.

3.8.5.4.3 Stability of Power Block Foundations

The integrated RB mat foundation stability is assessed against sliding and overturning due to SSE and extreme wind, and flotation following the guidance of Subsection II.4 of SRP 3.8.5.

Explicit sliding and overturning stability evaluations are not performed for the deeply embedded RB because, in accordance with Section 7.2 of ASCE/SEI 43-19, its center of gravity is located deep below the grade elevation, and the structure is inherently stable against sliding and overturning.

Required safety factors against sliding and overturning for the Power Block foundations under normal operating and accidental conditions are presented in Table 3.8-10. Safety factors listed in Table 3.8-10 conform to the allowable values specified in Subsection II.5 of SRP 3.8.5.

3.8.5.5 Structural Acceptance Criteria

The structural acceptance criteria for the containment and RB common mat foundation are the same as those for their respective superstructures described in Subsections 3.8.1.5 and 3.8.4.1.5. For safety factors considered for soil bearing and foundations stability, refer to Subsections 3.8.5.4.2 and 3.8.5.4.3, respectively.

3.8.5.6 Materials, Quality Control, and Special Construction Techniques

3.8.5.6.1 Materials

Materials used for the construction of the containment and RB common mat foundation are the same as those of the superstructures described in Subsections 3.8.1.6.1 and 3.8.4.1.6.

The common mat foundation DP-SC modules are designed with a sacrificial thickness to account for corrosion over the RB operating life as discussed in Subsection 3.8.4.1.6.

3.8.5.6.2 Quality Control

Refer to Subsections 3.8.1.6.2 and 3.8.4.1.6 for discussion.

3.8.5.6.3 Special Construction Techniques

Refer to Subsection 3.8.4.1.6 for discussion.

3.8.5.7 Testing and Inservice Surveillance Programs

The inspection and testing of the integrated RB mat foundation follow the guidance of Sections 3.2.2 and 3.4 of NEDO-33914-A, and Sections 5.18 and 6.22 of NEDC-33926P. The foundation testing and surveillance program complies with the requirements of 10 CFR 50.65 and guidance of RG 1.160 and includes the use of non-destructive testing and remote visual monitoring to monitor conditions in inaccessible areas of the foundation.

In accordance with Section 3.4 of NEDO-33914-A, field instrumentation is installed inside and outside of the RB to measure the distribution of pore pressures around and below the structure, total settlement and tilt of the RB including foundation, and measurement of the surrounding Power Block structures. The instrumentation provides recordings during excavation and

continuing through plant operation that can be benchmarked against design estimates using results of the FIA. Short-term and long-term settlement monitoring plans are also developed to detect:

- Vertical and horizontal movements in and around the integrated RB
- Differential distortion across the foundation footprint
- Differential settlements between the containment and RB portions of the mat foundation

Table 3.8-1 Load Combinations and Load Factors for Steel-Plate Composite Containment Vessel

Load Category	Combination #	Loads																		Load Condition
		D	F	L	H	P_t	T_t	P_v/P_o	R_o	T_o	W	E_s	W_t	P_a	R_a	T_a	Y_j/R_{rj}	Y_m/R_{rm}	Y_r/R_{rr}	
Test	SCCV-1	1.0	1.0	1.0	1.0	1.0	1.0													Service
Construction	SCCV-2	1.0	1.0	1.0	1.0					1.0	1.0									
Normal	SCCV-3	1.0	1.0	1.0	1.0			1.0	1.0	1.0										
Severe Environmental	SCCV-4	1.0	1.0	1.30	1.30			1.0	1.0	1.0	1.5									Factored
Extreme Environmental	SCCV-5	1.0	1.0	1.0	1.0			1.0	1.0	1.0		1.0								
	SCCV-6	1.0	1.0	1.0	1.0			1.0	1.0	1.0			1.0							
Abnormal	SCCV-7	1.0	1.0	1.0	1.0									1.5	1.0	1.0				
	SCCV-8	1.0	1.0	1.0	1.0									1.0	1.25	1.0				
	SCCV-9	1.0	1.0	1.0	1.0									1.25	1.0	1.0				
Abnormal / Extreme Environmental	SCCV-10	1.0	1.0	1.0	1.0						1.25			1.25	1.0	1.0				
	SCCV-11	1.0	1.0	1.0	1.0							1.0		1.0	1.0	1.0	1.0	1.0	1.0	

(1) The load combination involving post-LOCA flooding condition with OBE (set at 1/3 of the SSE, see Subsection 3.7.1) is eliminated in accordance with SRP 3.8.1. This load combination is bounded by SCCV-11 because the maximum hydrostatic pressure produced by the post-LOCA flooding is less significant than the accident LOCA pressure.

D = Dead Loads
F = Hydrostatic Pressure Loads
L = Live Loads
H = Soil and Underground Water Pressure Loads
P_t = Test Pressure Loads
T_t = Test Thermal Loads
P_v/P_o = Pressure Variant Load
R_o = Normal Operating Pipe Reaction Loads
T_o = Normal Operating Thermal Loads
W = Wind Loads
E_s = Seismic Loads (generated by SSE)
W_t = Tornado or Hurricane Loads
P_a = Accident Pressure Loads
R_a = Accident Pipe Reaction Loads
T_a = Accident Thermal Loads
Y_j/R_{rj} = Jet Impingement Loads
Y_m / R_{rm} = Missile Impact Loads
Y_r / R_{rr} = High-Energy Pipe Rupture

Table 3.8-2a Acceptance Criteria for BWRX-300 Steel-Plate Composite Containment Vessel

Allowable Stress/Strain Limits for Factored Loads

Material	Force Classification	Type of Force Action	Criteria for Factored Loads	
			Stress Limit	Strain Limit, if any
Concrete	Primary	Membrane	$0.60f_c'$	-
		Membrane + Bending (2)	$0.75f_c'$	-
	Primary + Secondary (1)	Membrane	$0.75f_c'$	-
		Membrane + Bending (2)	$0.85f_c'$ (3)	-
Steel Plates	Primary	Membrane or Membrane + Bending (2)	$0.90F_y$	-
	Primary + Secondary (1)	Membrane or Membrane + Bending (2)	-	$2\varepsilon_y$ (4)

(1) The primary portion of the calculated stress is not to exceed the allowable stress applicable when primary stress acts alone.

(2) The membrane portion of the calculated stress is not to exceed the allowable stress applicable when membrane stress acts alone.

(3) The maximum allowable primary-plus-secondary membrane and bending compressive stress of 0.85 f'c corresponds to a limiting strain of 0.002 in/in. The concrete allowable stresses for factored compression loads are reduced, if necessary, to maintain structural stability per CC-3421.1of ASME BPVC, Section III, Division 2.

(4) Limit for mechanical (net) strain due to primary forces, which is calculated by subtracting strain induced by secondary force from the total strain as per CC-3422.1(e) of ASME BPVC, Section III, Division 2. For analysis purposes, ϵ_y is defined as the yield stress divided by Young's modulus.

Table 3.8-2b Acceptance Criteria for BWRX-300 Steel-Plate Composite Containment Vessel

Allowable Stresses for Service Loads

Material	Force Classification	Type of Force Action	Criteria for Service Loads
			Stress Limit
Concrete	Primary	Membrane	$0.30f_c'$
		Membrane + Bending (2)	$0.45f_c'$
	Primary + Secondary (1)	Membrane	$0.45f_c'$
		Membrane + Bending (2)	$0.60f_c'$
Steel Plates	Primary	Membrane or Membrane + Bending (2)	$0.50F_y$ (3) (4)
	Primary + Secondary (1)	Membrane or Membrane + Bending (2)	$0.67F_y$ (3) (4)

(1) The primary portion of the calculated stress is not to exceed the allowable stress applicable when primary stress acts alone.

(2) The membrane portion of the calculated stress is not to exceed the allowable stress applicable when membrane stress acts alone.

(3) Where the steel plates are under tension stress, the stress limit may be increased by 50%, with an upper limit of $0.9F_y$ when the temporary pressure loads during the test condition are combined with other loads in the load combination.

(4) Where the steel plates are under compression stress, the stress limit may be increased by 33%, with an upper limit of $0.9F_y$ when the temporary pressure loads during the test condition are combined with other loads in the load combination.

Table 3.8-3 Load Combinations and Load Factors for Containment Closure Head

Service Level	Load Combination									
	D	**L**	**E_s**	**T_o**	**T_a**	**T_t**	**P_o**	**P_a**	**P_t**	**R_r**
Test Condition	1	1				1			1	
Design Condition	1	1			1			1		
Level A	1	1		1			1			
	1	1			1			1		
Level C	1	1	1		1			1		
	1	1	1	1			1			
Level D	1	1	1		1			1		1

(1) Based on SRP 3.8.2 and RG 1.57

(2) D = Dead Load

L = Live Load

E_s = Seismic Loads (generated by SSE)

T_o = Normal Operating Thermal Loads

T_a = Accident Thermal Loads

T_t = Test Thermal Loads

P_o = Normal Operating Pressure Loads including Pressure Variant Loads (P_v)

P_a = Accident Pressure Loads

P_t = Test Pressure Loads

R_r = Local Effects on Containment due to LOCA (R_{rj} + R_{rm})

(3) As per RG 1.216, combustible gas load cases (Pg1, Pg2, and Pg3) and associated load combinations are associated with DECs and are currently not presented in this table. The structural integrity of the containment closure head is demonstrated by meeting the requirements in ASME BPVC, Section III, Subsection NE for the applicable load combinations comprising of dead load and internal pressure specified in RG 1.57 with a minimum internal pressure of 310 kPa (45 psig).

Table 3.8-4 Load Combinations and Load Factors for Class MC Components

Service Level	Load Combination												
	D	L	E_s	T_o	T_a	T_t	P_o	P_a	P_t	R_r	R_o	R_a	H_a
Test Condition	1	1				1			1				
Design Condition	1	1			1			1				1	
Level A	1	1		1			1				1		
	1	1			1			1				1	
Level C	1	1	1		1			1				1	
	1	1	1	1			1				1		
Level D	1	1	1		1			1		1		1	
Post-flooding Condition	1	1	1[2]										1

(1) Based on SRP 3.8.2 and RG 1.57

(2) OBE consideration only for post-flooding conditions and cyclic loading considerations, in accordance with SRP 3.8.2

(3) D = Dead Load

L = Live Load

E_s = Seismic Loads (generated by SSE)

T_o = Normal Operating Thermal Loads

T_a = Accident Thermal Loads

T_t = Test Thermal Loads

P_o = Normal Operating Pressure Loads including Pressure Variant Loads (Pv)

P_a = Accident Pressure Loads

P_t = Test Pressure Loads

R_r = Local Effects on Containment due to LOCA (Rrr + Rrj + Rrm)

R_o = Normal Operating Pipe Reaction Loads

R_a = Accident Pipe Reaction Loads

H_a = Internal Flooding Loads

(4) In accordance with RG 1.216, combustible gas load cases (Pg1, Pg2, and Pg3) and associated load combinations are associated with DECs and are currently not presented in this table. The structural integrity of the Class MC components is demonstrated by meeting the requirements in ASME BPVC, Section III, Subsection NE for the applicable load combinations comprising of dead load and internal pressure specified in RG 1.57 with a minimum internal pressure of 310 kPa (45 psig).

Table 3.8-5 Acceptance Criteria for Containment Closure Head

Service Level	Acceptance Criteria*1			
	P_m	P_L	P_L+P_b *2	P_L+P_b+Q
Test Condition	0.8 S_y	1.15 S_y	1.15 S_y	N/A*3
Design Condition	1.0 S_{mc}	1.5 S_{mc}	1.5 S_{mc}	N/A*3
Level A	1.0 S_{mc}	1.5 S_{mc}	1.5 S_{mc}	3.0 S_m
Level C	1.2 S_{mc} or*4 1.0 S_y	1.8 S_{mc} or*4 1.5 S_y	1.8 S_{mc} or*4 1.5 S_y	N/A*3
Level D	S_f	1.5 S_f	1.5 S_f	N/A*3

*1: Acceptance Criteria is defined by ASME BPVC, Subsection NE, NE-3221.1 through 3221.4.

P_m = primary stress: general membrane.

P_L = primary stress: local membrane.

P_b = primary stress: bending.

Q = secondary stress: membrane plus bending.

S_y = material's yield strength at temperature as in ASME BPVC, Section II, Part D, Table Y-1.

S_m = allowable stress intensity S_m is the value given in ASME BPVC, Section II, Part D, Subpart 1, Tables 2A and 2B.

S_{mc} = allowable stress intensity S_{mc} is 1.1 times the S listed in ASME BPVC, Section II, Part D, Subpart 1, Tables 1A and 1B, except S_{mc} is not to exceed 90% of the material's yield strength at temperature shown in ASME BPVC, Section II, Part D, Subpart 1, Table Y-1.

S_f = 85% of the general primary membrane allowable permitted in Mandatory Appendix XXVII of ASME BPVC, Section III. In the application of Appendix XXVII, S_m, if applicable, is as specified in NE-3112.4(a)(1).

*2: Values shown are for a rectangular section. See ASME BPVC, Subsection NE, NE-3221.3(d) for other than a solid rectangular section.

*3: N/A = Not applicable. No evaluation required.

*4: The larger of the two values listed is chosen as a limit load.

Table 3.8-6 Acceptance Criteria for Other Class MC Components

Service Level	Acceptance Criteria*1			
	P_m	P_L	P_L+P_b *2	P_L+P_b+Q
Test Condition	0.8 S_y	1.15 S_y	1.15 S_y	N/A*3
Design Condition	1.0 S_{mc}	1.5 S_{mc}	1.5 S_{mc}	N/A*3
Level A	1.0 S_{mc}	1.5 S_{mc}	1.5 S_{mc}	3.0 S_m
Level C	1.2 S_{mc} or*4 1.0 S_y	1.8 S_{mc} or*4 1.5S_y	1.8 S_{mc} or*4 1.5 S_y	N/A*3
Level D	S_f	1.5 S_f	1.5 S_f	N/A*3
Post-flooding Condition	1.2 S_{mc} or*4 1.0 S_y	1.8 S_{mc} or*4 1.5 S_y	1.8 S_{mc} or*4 1.5 S_y	3.0 S_m

*1: Acceptance Criteria for other than Post-flooding Condition is defined by ASME BPVC, Subsection NE, NE-3221.1 through 3221.4. For Post-flooding Condition, Service Level C limits apply to primary stress, and Service Level B limits apply to primary plus secondary stress, per item 5 of SRP 3.8.2.

P_m = primary stress: general membrane.

P_L = primary stress: local membrane.

P_b = primary stress: bending.

Q = secondary stress: membrane plus bending.

S_y = material's yield strength at temperature as in ASME BPVC, Section II, Part D, Table Y-1.

S_m = allowable stress intensity S_m is the value given in ASME BPVC, Section II, Part D, Subpart 1, Tables 2A and 2B.

S_{mc} = allowable stress intensity S_{mc} is 1.1 times the S listed in ASME BPVC, Section II, Part D, Subpart 1, Tables 1A and 1B, except S_{mc} is not to exceed 90% of the material's yield strength at temperature shown in ASME BPVC, Section II, Part D, Subpart 1, Table Y-1.

S_f = 85% of the general primary membrane allowable permitted in Mandatory Appendix XXVII of ASME BPVC, Section III. In the application of Appendix XXVII, S_m, if applicable, is as specified in NE-3112.4(a)(1).

*2: Values shown are for a rectangular section. See ASME BPVC, Subsection NE, NE-3221.3(d) for other than a solid rectangular section.

*3: N/A = Not applicable. No evaluation required.

*4: The larger of the two values listed is chosen as a limit load

Table 3.8-7 Load Combinations, Load Factors and Acceptance Criteria for Reactor Building Safety Class 1 Steel-Plate Composite Modules and Steel Structures
(Sheet 2 of 2)

(1) Load combinations are in accordance with ANSI/AISC N690 and RG 1.243. Load combination RB2/3 is a conservative bounding load combination for RB-2.1, RB- 2.2, RB-2.3, RB-3.1, RB-3.2, and RB-3.3 required by ANSI/AISC N690.

D = Dead Loads, including settlements

F = Hydrostatic Pressure Loads

L = Live Loads

H = Soil and Underground Water Pressure Loads

L_r = Roof Live Loads

R = Rain Loads

S = Snow Loads

C = Crane Loads

R_o = Normal Operating Pipe Reactions

P_o = Normal Operating Pressure Loads

T_o = Normal Operating Thermal Loads

W = Wind Loads

E_s = Seismic Loads (Generated by SSE)

W_t = Tornado or Hurricane Wind Loads

S_x = Extreme Snow Loads

P_a = Accidental Pressure Loads

R_a = Accidental Piping Reactions

T_a = Accidental Thermal Loads

Y_j = Jet Impingement Loads from a ruptured high-energy pipe

Y_m = Missile Impact Loads from a ruptured high-energy pipe

Y_r = High-Energy Pipe Rupture

(2) When Pa and Ta are time-dependent loads, their effects are superimposed accordingly.

(3) Loads due to accidental explosions, accidental vehicle impacts, extreme snow load, and small aircraft impacts are evaluated using load combination RB-6 with those loads in lieu of W_t, following the guidance provided in Appendix N9 of ANSI/AISC N690.

Table 3.8-8 As-Built Subgrade Properties for Static 1-g Soil-Structure Interaction and Impedance Analyses

Layer	Layer Thickness	Parameters for Static 1-g SSI Analysis (LB E_{st} & UB ν_{st})			Parameters for Static Impedance Analysis (LB E_{st} & LB ν_{st})

3.9 Mechanical Systems and Components

Section 3.9 provides the general design aspects used for Safety Class and Non-Safety Class (SCN) mechanical systems and components. It includes special considerations for mechanical components, dynamic testing and analysis of Structures, Systems, and Components (SSCs), required codes for American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code (BPVC), Section III, Division 1, Subsections NB and NCD for Class 1, 2, and 3 components, Subsection NF for component supports, and Subsection NG for core support structures. In addition, general design aspects for Control Rod Drive (CRD) system, and reactor vessel internals are presented. Further, this section discusses the functional design, qualification, and Inservice Testing (IST) program requirements for pumps, valves, and dynamic restraints. The design of SC2 and SC3 equipment follows ASME B31.1, “Power Piping,” (Reference 3.9-9) and ASME B31.3, “Process Piping,” (Reference 3.9-10).

Section 3.1 and 3.2 are used as input to Section 3.9 and provide the general design principles, criteria, and classification used for design of mechanical systems and components. Among these principles are design for robustness, reliability, and fail-safe operation.

Section 3.7 develops the seismic input criteria and building spectra used as input to Section 3.9 and Section 3.10 for seismic qualification of Seismic Category I active mechanical components and system functionality. Additionally, Seismic Category I passive mechanical component supports, and equipment supports use the seismic spectra for qualification.

Equipment qualification requirements are provided in Section 3.10 for seismic and dynamic qualification of mechanical and electrical equipment, and Section 3.11 provides the equipment qualification requirements including environmental, functional qualification, and Electromagnetic Compatibility (EMC), which are used as input to safety classified mechanical systems and components.

Mechanical Equipment Separation for Safety Class 1 (SC1) Equipment

Simultaneous occurrence of identical failures in multiple, redundant components of the same technology are called Common Cause Failures (CCF). CCFs are an important consideration in the safety design of nuclear reactors and are considered in hazard analysis. Means of avoiding CCFs in SC1 SSCs include separation, diversity, redundancy, and independence. Separation of SSCs can be achieved using either distance, barriers, or both. Separation is also needed between redundant SSCs that perform Safety Category 1 functions to help ensure that these functions cannot be fully disabled by internal or external hazards.

Mechanical equipment separation measures for the BWRX-300 contribute to system reliability in the performance of any Safety Category 1 function including (but not necessarily limited to) interconnecting Safety Class and SCN piping, valves, and associated mechanical controls, and instrumentation. Separation is also needed for plant features and functions where redundancy and independence are credited for ensuring acceptable safety analysis results.

Principles of physical separation include:

1. Separation by geometry (layout, distance, orientation, elevation, and, including separate structures)

2. Separation by barriers (e.g., walls, shields), both vertical and horizontal

3. Separation by a combination of (1) and (2)

The choice of the means of separation depends on the hazards considered in the design basis, such as floods, missiles, fires.

Protection against hazards is accomplished by:

- Use of structures
- Spatial separation
- Three-hour rated fire barriers
- Isolation devices

The application of the single failure criterion is described in NEDC-33934P, “BWRX-300 Safety Strategy,” (Reference 3.9-18).

Separation of components may be by physical distance or by barriers. An example is the provision of principal fire barriers to delineate individual fire zones; such barriers may also serve as barriers to other hazards.

The following Safety Class and SCN SSCs mechanical equipment items are considered for separation:

- Piping systems
- Valves
- Rotating equipment
- Vessels
- Ductwork systems
- Instrumentation

Piping Systems

Piping systems include piping to and from Safety Class and SCN SSCs. These include their connected bellows, mechanical connections, support guides, and structural supports. They may include wall or floor sleeves and penetrations, pipe fittings including wells and branch connections, structural restraints (and appurtenances), and attached sampling. Piping systems also include vent/drain/test/flush/clean-out taps, including closures, instrument sensing line piping or tubing, and instrument racks. Finally, they also include pneumatic or hydraulic system tubing, manifolds, and controls appurtenances.

Valves

Valves include those that control fluid flow to and from Safety Class and SCN SSCs. Valves include the valve body assembly, actuators, appurtenances, and all non-electrical connections.

Rotating Equipment

Rotating equipment includes Safety Class and SCN pumps, fans, and compressors, gear sets or power coupling subsystems, and electric motors or other rotary-power driven subsystems. Their components include rotating casing, including base, frame, supports, and drive.

Vessels

Vessels include Safety Class and SCN heat exchangers and tanks, including their supports, filter assemblies, and nozzles.

Ductwork Systems

Safety Class and SCN ductwork systems include:

- Duct runs
- Active and pre-set dampers
- Fire dampers
- Screens
- Vents/reliefs/blow out panels
- Filters or air filtration assemblies/subsystems

Instrumentation

Safety Class and SCN Instrumentation includes:

- Mechanically activated instruments used to monitor reactor and plant processes
- The associated non-electrical transmission
- Sensors
- Actuator systems
- In-line instruments with associated taps

Zone of Influence

The degree and type of separation required varies with the following potential hazards in a power plant zone:

1. Missiles – A missile is an unrestrained mass with sufficient kinetic energy to cause damage to SC1 components. Definition of missile and missile protection requirements are addressed in Section 3.5.

2. Pipe whip – Pipe whip is usually consequent to a pipe failure resulting in a complete segment separation break. The area in the vicinity of the postulated break of high-energy piping is defined as the pipe whip damage zone. Pipe whip protection requirements are addressed in Subsection 3.6.2.

3. Fluid jet – The fluid jet is usually consequent to a high-energy pipe break but may also be the result of intentional equipment action. Jet impingement protection requirements are addressed in Subsection 3.6.2.

Fire Area and Fire Zone

A fire area is an area sufficiently bounded to withstand the hazards associated with the fire area and to protect important equipment within the fire area from a fire outside the area. A fire zone, however, is a subdivision of fire area(s) for analysis purposes that is not necessarily bounded by fire-rated barriers.

Fire protection requirements are addressed in Subsection 9.5.1. Separation of vulnerable mechanical equipment from areas containing significant combustible materials is provided by fire barrier materials or housings, fire-rated walls, or doors (including consideration for ductwork isolations), barrier piping around processes containing flammable or combustible fluids to isolate the hazard, and in certain locations by atmospheric inerting (oxygen concentration suppression below combustible level or replacement with nitrogen, such as in containment).

Flood Zone

Internally generated flooding may occur by pipe or tank failure, fire suppression system operation, misaligned systems with openings in the affected zone, maintenance errors, or failure of a drainage system. Flood protection requirements are addressed in Section 3.4.

Separation by flood hazard containment walls, dikes, curbs, trenches or pits, watertight doors, elevated equipment mounting location (mezzanine or different floor), or pedestals, or placing vulnerable equipment in watertight housings may be used.

Design Load and Load Combination for Mechanical Systems and Components

Subsection 3.9.1.1 provides the operational transients, resulting loads, and load combinations.

Design loads and load combinations (including design bases accidents) for fixed mechanical equipment are provided in Table 3.9-3. Refer to Tables 3.12-1 through 3.12-10 for additional load combination tables. These tables address faulted level transients. Fixed equipment includes the mechanical, electrical, and instrument components, and the component housings and structural supports that are anchored to civil structure(s) but are not a part of the civil structure itself, such as mechanical or electrical penetrations. Examples include the Reactor Pressure Vessel (RPV), RPV internals, RPV supports, instrumentation, piping, electrical equipment, and the component supports.

For SC1 containment structure penetrations, the anchor sleeve, where the sleeve itself acts as a containment boundary, is to meet the requirements of ASME BPVC, Section III, Subsection NE, “Class MC Components,” (Reference 3.9-5).

Design for System Duty of Mechanical Systems Based on Frequency of Occurrence and Plant State

Table 3.9-1 is used as a general event list for all hardware system duty design specifications. Service Levels are classified into service conditions as indicated below based on frequency of occurrence and plant state:

- Normal: Planned Operation
- Upset: Anticipated Operational Occurrence (AOO)
- Emergency: Design Basis Accident (DBA) of low frequency
- Faulted: DBA of very low frequency

The BWRX-300 utilizes the four service levels used in ASME BPVC Section III, Division 1 and 2, Subsection NCA, “General Requirements for Division 1 and Division 2,” (Reference 3.9-4), Levels A, B, C and D, as well as testing conditions, in the design of fixed equipment. The design basis specifies the capabilities that are necessary for the plant in various operational states.

3.9.1 Special Topics for Mechanical Components

This subsection addresses information concerning methods of analysis for Seismic Category I components and supports, including those designated as ASME BPVC, Section III, Class 1, 2, 3, or Core Support Structures and those not covered by the ASME BPVC as discussed in SRP 3.9.1. Information is also presented concerning design transients for ASME BPVC Class 1 and Core Support components and supports.

The BWRX-300 design complies with the following GDC, which have plant-wide applicability, as discussed in Section 3.1:

GDC 1 – Quality standards and records

GDC 2 – Design bases for protection against natural phenomena

The following GDC have aspects specific to the BWRX-300 design and compliance is addressed as follows:

GDC 14 – Reactor coolant pressure boundary. The Reactor Coolant Pressure Boundary (RCPB) is designed, fabricated, erected, and tested so as to have an extremely low probability of abnormal leakage, of rapidly propagating failure, and of gross rupture. The design involves meeting the ASME BPVC, Section III acceptance criteria utilizing load combinations in Table 3.9-3 including transient plant duty cycles in Table 3.9-2 for the plant lifetime to assure minimal abnormal leakage.

GDC 15 – Reactor coolant system design. The mechanical components of the Reactor Coolant System (RCS) and associated auxiliary, control, and protection systems are designed with sufficient margin to ensure that the design conditions of the RCPB are not exceeded during any condition of normal operation, including AOO and DBA event sequences. Subsection 3.9.1 through Subsection 3.9.6 provide design requirements for Safety Class mechanical components that meet the margin and design condition requirements, therefore complying with GDC 15.

Section 3.1 summarizes compliance with GDC.

10 CFR 50, Appendix B, as it relates to design quality control, is discussed in Section 17.1.

10 CFR 50, Appendix S, as it relates to the suitability of the plant design bases for mechanical components established in consideration of site seismic characteristics, is discussed in Section 3.7.

Instrument sensing lines conform to the guidelines of RG 1.151, “Instrument Sensing Lines.”

3.9.1.1 Design Transients

The plant duty cycles represent transient events and their associated number of occurrences for the 60-year plant design life. These duty cycles are used for development of the BWRX-300 system and component design during normal operation, AOO and DBA. Requirements are evaluated for the system design and performance as they relate to complete reactor operation. The duty cycle is recorded as inputs to the system design for each specific primary and auxiliary hardware system. Duty is defined from a pressure and temperature perspective, mostly when variations in either variable are expected in important locations for the reactor including the RCPB and connecting piping and components.

The number of cycles associated with each event for the design of the RPV, RCPB, and other ASME pressure boundary components designed for fatigue are listed in Table 3.9-2. Table 3.9-1 breaks down the plant states by design condition. The plant operating conditions are identified as Normal, AOO, DBA, or testing as defined in Subsection 3.9.3.3. Appropriate service levels (A, B, C, D, or testing), as defined in the ASME BPVC, are designated for design limits. The design and analyses of ASME class piping and equipment using specific applicable thermal-hydraulic transients, which are derived from the system behavior during the events listed in Table 3.9-2 are documented in the design specifications and/or stress reports of the respective equipment. Table 3.9-3 shows the load combinations and the standard acceptance criteria for ASME Section III components. Tables 3.12-1 through 3.12-10 provide the specific load combinations and acceptance criteria for ASME BPVC Section III Class 1, 2, and 3, B31.1, and B31.3 piping systems. Details about ASME B31.5, “Refrigeration Piping and Heat Transfer Components,” (Reference 3.9-19) piping is addressed in Section 3.12.

3.9.1.2 Computer Programs Used in Analyses

The computer programs described in Appendix 3J are used in the mechanical system and component analyses of the SC1 components, as listed in Table 3A-1.

The computer programs used in the analyses of Seismic Category I components are maintained by GEH or by outside computer program developers.

The GEH software is controlled under NEDO-11209-A, “GE Hitachi Nuclear Energy Quality Assurance Program Description,” (Reference 3.9-12). The programs are verified for their application by appropriate methods, such as hand calculations, or comparison with results from similar programs, experimental tests, or published literature.

3.9.1.3 Experimental Stress Analysis

Experimental stress analysis methods are used in compliance with the provisions of ASME BPVC, Section III, “Appendices,” (Reference 3.9-1).

3.9.1.4 Considerations for the Evaluation of Fault Conditions

Equipment designed to ASME BPVC, Section III, is evaluated for the faulted (Service Level D) loading conditions. In these cases, the calculated actual stresses are compared to the allowable ASME BPVC, Section III Service Level D limits. Analysis of ASME BPVC Class 1 components, component supports, core support structure components and reactor internals, and other non-code items, demonstrates that GDC 1, 14, and 15 requirements are met under faulted conditions when Service Level D limits are specified. The methods of analysis to calculate the stresses and deformations should conform to the methods outlined in the ASME BPVC, Section III, Mandatory Appendix XXVII, “Design by Analysis for Service Level D,” subject to the conditions addressed in Subsection II of SRP 3.9.1. ASME QME-1, “Qualification of Active Mechanical Equipment Used in Nuclear Facilities,” (Reference 3.9-15) is used for functional qualification of valves.

Deformations under faulted conditions are evaluated in critical areas and the necessary design deformation limits, such as clearance limits, are satisfied.

The following subsections address the evaluation methods and stress limits used for the equipment and identify the components evaluated for faulted conditions.

3.9.1.4.1 Fine Motion Control Rod Drive

The Fine Motion Control Rod Drive (FMCRD) components that are part of the RCPB are analyzed and evaluated for the ASME Service Level D faulted conditions in accordance with the ASME BPVC, Section III, Subsection NB, “Class 1 Components” (Reference 3.9-2). Refer to Section 4.6 for FMCRD mechanism details.

3.9.1.4.2 CRD Hydraulic Control Unit

The Hydraulic Control Unit (HCU) is analyzed and tested for withstanding the faulted condition loads. Dynamic tests that are part of the seismic and dynamic qualification program establish the loads in the horizontal and vertical directions as the HCU capability for the frequency range that is likely experienced in the plant. These tests also ensure that the reactor trip function of the HCU

can be performed under these loads. Dynamic analysis of the HCU with the mounting beams is performed to assure that the maximum faulted condition loads remain below the HCU capability. Refer to Section 4.6 for HCU description details.

3.9.1.4.3 Reactor Pressure Vessel Assembly

The design of the RPV assembly as shown in Figure 4.1-1, out to and including the integral Reactor Isolation Valves (RIV), RPV top head, housings for FMCRD, and incore nuclear instrumentation complies with Subsections NB and NG of the ASME BPVC, Section III, as applicable. For faulted conditions, the reactor vessel is evaluated using elastic analysis.

Elastic analysis methods are defined in Section 3.7.3 and standard design rules, as defined in the ASME BPVC, are utilized in the analysis of the pressure boundary valves. The ASME BPVC, Section III allowable stress is applied to assure integrity under applicable loading conditions including faulted conditions. The functional qualification for the RIV, includes analysis and/or testing for seismic and other dynamic conditions.

3.9.1.4.4 Core Support Structures and Other Safety Class Reactor Internal Components

The core support structures, the internal portion of nuclear instrument, and CRD housings and other SC1 reactor internal components are evaluated for faulted conditions. The allowable Service Level D limits for evaluation of these structures are per ASME BPVC, Section III Service Level D equations and Subsection NG, “Core Support Structures” (Reference 3.9-7).

For the shroud support, an elastic analysis is performed, and buckling is evaluated for compressive load cases for certain locations in the assembly.

3.9.1.4.5 RPV Stabilizers, Reactor Skirt and FMCRD Housing and Nuclear Instrumentation Housing Restraints (Supports)

The calculated maximum stresses to meet the allowable stress limits are based on the ASME BPVC Section III, Subsection NF, “Supports,” (Reference 3.9-6), for the RPV Stabilizer, RPV Skirt, and supports for the FMCRD Housing, and nuclear instrumentation housing for faulted conditions. These supports restrain the components during earthquake, pipe rupture or other reactor building vibration events.

3.9.1.4.6 Reactor Isolation Valves and Other ASME BPVC, Section III, Class 1 and 2 Valves

Elastic analysis methods and standard design rules, as defined in the ASME BPVC, are utilized in the analysis of the pressure boundary, Seismic Category I, ASME Class 1 and Class 2 valves. The ASME BPVC, Section III allowable stresses are applied to assure integrity under applicable loading conditions including faulted conditions. The functional qualification of the active valves, including RIVs; Containment Isolation Valves (CIV); Isolation Condenser System (ICS) valves (steam supply, standby gas purge, and condensate return valves) includes analysis and/or testing for seismic and/or other dynamic conditions.

3.9.1.4.7 Fuel Storage and Refueling Equipment

The Fuel Storage and Fuel Handling equipment is described in detail in Section 9.1. This includes the fuel pool structure, fuel racks, fuel pool cooling system, and fuel handling equipment.

A summary of the design considerations used to establish nuclear criticality safety under all operational and faulted (ASME Service Level D) conditions is described below.

All fuel racks are designed and qualified to operate within their performance requirements under the anticipated ranges of the normal, abnormal, or accident plant environments and are designed to withstand a Safe Shutdown Earthquake (SSE) without failure of the basic structure or damage to the active region of irradiated fuel.

3.9.1.4.8 Fuel Assembly (Including Channel)

The fuel assembly (including channel) is described in detail in Section 4.2.

The channel is subjected to mechanical tests to demonstrate the adequacy of the Global Nuclear Fuel (GNF)2 channel for seismic/dynamic loads. The channel is tested to determine the allowable bending load that is sustained without buckling or collapsing the channel.

The fuel assemblies are designed for worst-case conditions that evaluate maximum stresses, fatigue, control rod insertion, fretting, corrosion/hydriding, and compatibility/dimensional changes. The results of the testing and analysis require that the SC1 components maintain the required functionality and structural capacity during ASME Level D service conditions.

3.9.1.4.9 ASME BPVC, Section III, Class 2 and 3 Vessels

The equivalent allowable stresses using elastic techniques are obtained from NCD-3300 and NCD-3200 of the ASME BPVC, Section III, Subsection NCD “Class 2 and Class 3 Components” (Reference 3.9-3).

3.9.1.4.10 ASME Class 2 and 3 Pumps

Elastic analysis methods defined in Section 3.7.3.1 are used for evaluating faulted loading conditions for Class 2 and Class 3 pumps. The equivalent allowable stresses for pumps using elastic techniques are obtained from NCD-3400. The preliminary SSC classification list in Table 3A-1 does not identify any pumps to be ASME Class 2 or Class 3 currently.

3.9.1.4.11 ASME Class 2 and 3 Valves

Elastic analysis methods defined in Section 3.7.3.1 and standard design rules are used for evaluating faulted loading conditions for Class 2 and 3 valves. The equivalent allowable stresses for valves using elastic techniques are obtained from NCD-3500.

3.9.1.4.12 ASME Class 1, 2 and 3 Piping

Elastic analysis methods defined in Section 3.7.3.1 are used for evaluating faulted loading conditions for Class 1, 2, and 3 piping. The equivalent allowable stresses using elastic techniques are obtained from NB-3600 (for Class 1 piping) and NCD-3600 (for Class 2 and 3 piping).

3.9.1.4.13 Inelastic Analysis Methods

The design criteria for pipe failure effects and mitigating features are provided in Section 3.6. Inelastic methods are not used in BWRX-300 piping design as described in Subsection 3.12.1.5.

3.9.2 Dynamic Testing and Analysis of Systems, Components, and Equipment

This subsection presents the criteria, testing procedures, and dynamic analyses employed to ensure the structural and functional integrity of piping systems, mechanical equipment, reactor internals, and their supports (including supports for conduit and cable trays, and ventilation ducts) under vibratory loadings, including those due to fluid flow and postulated seismic events discussed in SRP 3.9.2. Structural requirements for conduits and cable tray supports and Heating, Ventilation, and Cooling System (HVS) duct supports are specified in Subsection 3.9.2.2.

Dynamic testing and analysis of systems, components and equipment complies with the following GDC, which have plant-wide applicability, as discussed in Section 3.1:

GDC 1 – Quality standards and records

GDC 2 – Design bases for protection against natural phenomena

GDC 4 – Environmental and dynamic design bases

The following GDC have aspects specific to Subsection 3.9.2 and compliance is addressed as follows:

GDC 14 – Reactor coolant pressure boundary. The Reactor Coolant Pressure Boundary (RCPB) is designed, fabricated, erected, and tested so as to have an extremely low probability of abnormal leakage, of rapidly propagating failure, and of gross rupture. The design involves meeting the ASME BPVC, Section III acceptance criteria utilizing load combinations in Table 3.9-3 including transient plant duty cycles in Table 3.9-2 for the 60-year life period to assure minimal abnormal leakage.

GDC 15 – Reactor coolant system design. The mechanical components of the Reactor Coolant System (RCS) and associated auxiliary, control, and protection systems being designed with sufficient margin to ensure that the design conditions of the RCPB are not exceeded during any condition of normal operation, including AOO and DBA event sequences. Subsection 3.9.1 through Subsection 3.9.6 provide design requirements for Safety Class mechanical components that meet the margin and design condition requirements, therefore complying with GDC 15.

Additional Information on GDC compliance is found in Section 3.1.

10 CFR 50, Appendix B, as it relates to design quality control, is discussed in Section 17.1.

10 CFR 50, Appendix S, as it relates to the suitability of the plant design bases for mechanical components established in consideration of site seismic characteristics, is discussed in Section 3.7.

3.9.2.1 Flow Induced Vibration, Thermal Expansion, and Dynamic Effects

Piping vibration, thermal expansion, and dynamic effects testing is performed in accordance with the startup administrative manual as described in Chapter 14 and follows guidance from ASME OM Code, Nonmandatory Appendix M (Reference 3.9-11).

3.9.2.2 Seismic Qualification of SC1 Mechanical Equipment (Including Other Reactor Building Vibration Induced Loads)

This subsection discusses the testing and analytical qualification of the SC1 mechanical equipment, and other ASME BPVC, Section III equipment including equipment supports.

3.9.2.2.1 Tests and Analysis Criteria and Methods

The testing and analytical criteria for the seismic qualification of SC1 mechanical equipment are discussed in Section 3.10.

3.9.2.3 Dynamic Response Analysis of Reactor Internals Under Operational Flow Transients and Steady-State Conditions

The reactor internal components within the vessel are subjected to extensive dynamic system analysis and testing to evaluate the dynamic response of the components during normal reactor operation (i.e. steady state conditions) and operational flow transients. The main concern for steady state dynamic response is to ensure that flow-induced vibration (FIV) experienced during normal operation will not cause structural failure or degradation. FIV analysis is performed as explained in the following paragraph. Component loads due to operational flow transients and non-normal operational transient conditions are performed by analysis, as described in Section 3.9.2.5.

As a FIV scoping activity, reactor internal components are evaluated by analytical calculations to identify any components that may require design changes. Vibration levels of each component are scaled based on legacy BWR plant measurements as detailed below. Analytical calculations are performed as stated below and follow the four main FIV mechanisms that occur in BWR’s:

Turbulence forcing function scaling was performed on existing (legacy) BWR component measured strains, flows and frequencies. The BWRX-300 component strain (and stress) is calculated from scaling the legacy plant conditions and component natural frequencies to the BWRX-300 conditions and component natural frequencies. Turbulence forcing function scaling uses the fundamental flow physics laws:

- Turbulence pressure is a function of the square of flow velocity.
- Turbulence pressure decreases with increasing frequency. Turbulence loading is broadband and typically the largest response is at the component natural frequency.
- Vortex shedding (Strouhal) calculations on BWRX-300 components. This calculation also uses flow velocity past the structure compared to the structural natural frequency to ensure no lock-in occurs. This analysis follows ASME BPVC, Nonmandatory Appendix N, “Dynamic Analysis Methods.”
- There are no vane passing frequency FIV loads since there are no recirculation pumps.
- There are no slip joint leakage FIV loads since there are no slip joints in the BWRX RPV.

In addition, prior to initiation of the instrumented vibration measurement program, additional dynamic analyses of the reactor internals are performed. The results of these analyses are used to generate the allowable vibration levels during the vibration test.

3.9.2.4 Preoperational Flow-Induced Vibration Testing of Reactor Internals

The FIV program description has been developed in accordance with RG 1.20, “Comprehensive Vibration Assessment Program (CVAP) for Reactor Internals During Preoperational and Startup Testing,” to verify the adequacy of the reactor vessel internals with respect to FIV. The CVAP establishes the required testing for the reactor internals in accordance with RG 1.20 to ensure that flow-induced vibrations experienced during normal operation will not cause structural failure or degradation.

Most of the BWRX-300 RPV internals SSCs are classified as “limited prototype” per RG 1.20 since the components are scaled versions of components in existing legacy BWR plants. The limited prototype components are:

- Steam Separator Assembly
- Chimney
- Shroud
- Feedwater Piping and Sparger
- Core Plate
- Isolation Condenser Return Piping
- Steam Dryer

Although the steam dryer is a scaled version of the latest steam dryer technology, a full measurement program will be implemented because of the new piping/orifice arrangement and different steam dome acoustics.

New components included in the BWRX-300 design are the Reactor Water Cleanup Piping and the Head Vent piping. These components are classified as “prototype” per RG 1.20.

The first operational BWRX-300 will implement a measurement program during initial startup for all prototype and limited prototype elements in accordance with RG 1.20. The primary purpose of this test series is to verify the anticipated effect of single- and two-phase flow on the vibration

response of internals and to ensure these effects are within acceptable FIV criteria developed through the supporting dynamic analysis. Startup testing of the reactor internals is performed per the Initial Test Program (ITP) (Chapter 14).

For the initial prototype plant:

- Vibration measurements are recorded at incremental hold points up to and including up to 100% rated power during startup testing. The startup data will be recorded at plant steady state conditions at each hold point since FIV is a high cycle fatigue load. Measurements will occur during power ascension and will encompass the plant operational core-power map. It is anticipated that data will be recorded at 5% power increments, i.e. steady state hold points, during power ascension testing. The data recorded at each hold point is of sufficient duration to identify FIV mechanisms and to validate the analytical results.
  - There are no expected normal operation FIV transient loads since the BWRX-300 is a natural recirculation BWR, but if it is determined there is a need to measure transients between the hold points, then transient data will be recorded.
- Following completion of vibration measurement program, a final vibration testing report will be issued in accordance with RG 1.20.
- Following the initial startup test program, reactor internal components will be inspected at the end of the first cycle to identify any indications of FIV per RG 1.20. Anomalies, such as excessive wear, will be noted and a plan for mitigation will be developed. A final inspection report will be issued in accordance with RG 1.20.

Following completion of the measurement program, the CVAP will be presented to the NRC for review and acceptance as “valid” prototypes.

3.9.2.5 Dynamic System Analysis of Reactor Internals Under Faulted Conditions

Faulted Conditions are generally the bounding transients in BWR’s. Because these transients cannot be simulated in a working BWR, these events are analyzed and not measured. It should be noted that all transients, including anticipated operational occurrences, emergency and faulted conditions are analyzed to ASME BPVC, Section III and ASME Service Level definitions. Refer to Section 3.9.3.1 on Loads and Load Combinations. The dynamic analysis for faulted conditions events considers the following:

- Reactor Internal Pressures
- External Pressure and Forces on the Reactor Vessel
- Loss-of-Coolant Accident (LOCA) Loads
- Seismic Loads

These resulting loads to the reactor internals are included in the deterministic analysis performed for faulted conditions and described further in Section 3.9.3.

3.9.2.6 Correlations of Reactor Internals Vibration Tests with the Analytical Results

Prior to initiation of the instrumented vibration measurement program, extensive dynamic analyses of the reactor and internals are performed as described in Section 3.9.2.3 and 3.9.3.5. The results of these analyses are used to generate the allowable vibration levels during the vibration test. The vibration data obtained during the test are analyzed in detail.

The results of the data analyses, vibration amplitudes, natural frequencies, and mode shapes are then compared to those obtained from the theoretical analysis.

Such comparisons provide the analysts with added insight into the dynamic behavior of the reactor internals. In addition, knowledge gained from previous vibration tests is used in the generation of updated dynamic models for seismic and LOCA analyses of the plant. The models used for the BWRX-300 are similar to those used for the vibration analysis of earlier prototype BWR plants. This section will be further developed in the FSAR stage.

3.9.3 ASME Class 1, 2, and 3 Components, Component Supports, and Core Support Structures

This subsection discusses the structural integrity and/or functional integrity requirements of pressure-retaining components, their supports, and core support structures that are designed in accordance with the rules of ASME BPVC, Section III, Subsections NB, NCD, NE, NF, and NG and GDC 1, 2, 4, 14, and 15 and 10 CFR 50 Appendix 5.

ASME Class 1, 2, and 3 Components, Component Supports, and Core Support Structures complies with the following GDC, which have plant-wide applicability, as discussed in Section 3.1:

GDC 1 – Quality standards and records

GDC 2 – Design bases for protection against natural phenomena

GDC 4 – Environmental and dynamic design bases

The following GDC have aspects specific to Subsection 3.9.3 and compliance is addressed as follows:

GDC 14 – Reactor coolant pressure boundary. The Reactor Coolant Pressure Boundary (RCPB) is designed, fabricated, erected, and tested so as to have an extremely low probability of abnormal leakage, of rapidly propagating failure, and of gross rupture. The design involves meeting the ASME BPVC, Section III acceptance criteria utilizing load combinations in Table 3.9-3 including transient plant duty cycles in Table 3.9-2 for the plant lifetime to have an extremely low probability of abnormal leakage.

GDC 15 – Reactor coolant system design. The mechanical components of the Reactor Coolant System (RCS) and associated auxiliary, control, and protection systems being designed with sufficient margin to ensure that the design conditions of the RCPB are not exceeded during any

condition of normal operation, including AOO and DBA event sequences. Subsection 3.9.1 through Subsection 3.9.6 provide design requirements for Safety Class mechanical components that meet the margin and design condition requirements, therefore complying with GDC 15.

Additional Information on GDC compliance is found in Section 3.1.

10 CFR 50, Appendix S, as it relates to the suitability of the plant design bases for mechanical components established in consideration of site seismic characteristics, is discussed in Section 3.7.

3.9.3.1 Loading Combinations, Design Transients, and Stress Limits

Subsection 3.9.3.3 delineates the criteria for selection and definition of design limits and loading combinations associated with Normal Operation, AOO, DBAs, and specified seismic and other RBV events for the design of ASME BPVC Section III components (except containment components which are discussed in Section 3.8).

This section discusses the ASME BPVC, Section III Class 1, 2, and 3 equipment and associated pressure-retaining parts, and identifies the applicable loadings, calculation methods, calculated stresses, and allowable stresses. A discussion of equipment is included on a component-by-component basis to provide examples. Design transients and dynamic loading for ASME BPVC, Section III Class 1, 2 and 3 equipment are covered in Subsection 3.9.1.1, Subsection 3.9.3.6, and Subsection 3.9.3.7. Seismic-related loads and methodology for seismic qualification are discussed in Subsection 3.7.3. Table 3.9-3 presents the plant events to be considered for the design and analysis of all BWRX-300 ASME BPVC, Section III Class 1, 2, and 3 components, component supports, and core support structures. Specific loading combinations considered for evaluation of specific equipment are derived from Table 3.9-3 and are contained in the design specifications and design reports for the respective equipment. For ASME Class 1 components where analysis for cyclic operation is evaluated in accordance with NB-3222.4, the fatigue usage evaluation includes the use of environmental fatigue curves in accordance with RG 1.207 and NUREG/CR-6909, “Effect of LWR Environments on the Fatigue Life of Reactor Materials.”

Specific load combinations and acceptance criteria for ASME Class 1, 2, 3, B31.1, and B31.3 piping is shown in Tables 3.12-1, 3.12-2, 3.12-3, and 3.12-4. Also, for ASME Class 1 piping, the operating temperatures above ambient or below ambient are included in the fatigue analysis. The installation temperature state for the piping system is defined as a temperature of 21°C (70°F) for Class 1, 2, 3 or ASME B31.1 piping.

The design life for the BWRX-300 Standard Plant is 60 years. A 60-year design life is a requirement for all plant components. Additional life is added for components required during decommissioning. The design life requirement allows for replacement, refurbishment, and repair, as appropriate, to assure that the design life of the overall plant is achieved.

3.9.3.2 Design and Installation of Pressure Relief Devices

NEDC-33910P-A, “BWRX-300 Reactor Pressure Vessel Isolation and Overpressure Protection,” (Reference 3.9-16) describes the methodology that is stated within ASME BPVC, Section III requirements for pressure relief. The BWRX-300 utilizes the ICS for RPV Pressure Relief as provided in Section 6.3.

3.9.3.3 Events Considered in Evaluating Effect of Loads on Fixed Equipment

Events that the BWRX-300 might credibly experience during a reactor-year are evaluated in Chapter 15, to establish the plant design basis, including plant fixed equipment. The associated loads and duty cycles associated with each event are considered in combination with additional events in load combinations as applicable. These event combinations are divided into the four plant conditions with associated frequency of occurrence and ASME BPVC, Section III service levels as shown in Table 3.9-1.

The following are the plant condition events and transients associated with the BWRX-300 design:

3.9.3.3.1 Normal Operation

See Table 3.9-3 for the Load Combinations and acceptance criteria which includes normal operation conditions.

3.9.3.3.2 Anticipated Operational Occurrences

See Table 3.9-3 for the Load Combinations and acceptance criteria which includes AOO conditions.

3.9.3.3.3 Design Basis Accident Events

See Table 3.9-3 for the Load Combinations and acceptance criteria which includes DBA events.

3.9.3.3.4 Seismic Events

Seismic design parameters and associated seismic events defined in Subsection 3.7.1 are used in qualification of mechanical system components which considers non-LOCA faulted and plant testing events. Section 3.10 provides seismic qualification methodology to assure both component structural and/or functional capacity under seismic operational conditions are met.

All SSCs of the BWRX-300 design are designated by Safety Class, Quality Group, and seismic category according to guidance in Section 3.2 and Table 3A-1 provides the classification table for plant SSCs.

3.9.3.4 Establishment of Design, Service, and Test Loadings and Limits

Design, Service, and Test Loadings and Limits for fixed equipment components and supports are in accordance with ASME BPVC, Section III, Subsection NCA.

SC1 electrical equipment is evaluated with respect to the load combinations in Table 3.9-3 using guidance in International Electrotechnical Commission (IEC)/Institute of Electrical and Electronics Engineers (IEEE) 60780-323, “Nuclear Facilities – Electrical Equipment Important to Safety – Qualification,” (Reference 3.9-13) and IEC/IEEE 60980-344, “Nuclear Facilities – Equipment Important to Safety – Seismic Qualification,” (Reference 3.9-14).

For SC1, actuators and power operated valve assemblies are evaluated with respect to the load combinations in accordance with the provisions of ASME QME-1. In addition to meeting ASME QME-1, SC1 actuators should consider the qualification guidance provided in IEEE 382 as endorsed by RG 1.73, “Qualification of Safety-Related Actuators in Production and Utilization Facilities” for their qualification program.

3.9.3.5 Acceptance Criteria

Components and supports comply with the design rules established for design, service, and test loadings in the appropriate subsection of ASME BPVC, Section III.

Design documentation is completed in accordance with the requirements of the subsection of ASME BPVC applicable to the component or support.

3.9.3.6 Loading Criteria

3.9.3.6.1 Loading Conditions

As appropriate, ASME BPVC, Section III, NB-3111, NCD-3111, NE-3111, NF-3111, or NG-3111, is applied for a complete list of required load conditions to consider.

Consistent with the ASME BPVC, Section III, the stresses resulting from differential anchor movements during dynamic events are considered secondary stresses. Refer to Subsections 3.7.3.1.4 and 3.7.3.9 for guidance.

The combinations of events and acceptance criteria are shown in Table 3.9-3. The method of combination of the loads is in accordance with NUREG 0484, “Methodology for Combining Dynamic Responses.”

3.9.3.6.2 Design Loadings

The Design Loadings are established in accordance with NB-3112, NCD-3112, NE-3112, NF-3112, or NG-3112, as applicable.

Design Pressure – The specified internal and external Design Pressure is not to be less than the maximum difference in pressure between the inside and outside of the item, or between any two chambers of a combination unit, which exists under the most severe loadings for which the Level A Service Limits are applicable.

The Design Pressure includes allowances for pressure surges. Note this is referred to as Design Pressure Difference in NG-3112 for core support structures.

Design Temperature – Except as otherwise defined in NB-3112 for Class 1 components, the specified Design Temperature is not less than the expected maximum mean metal temperature through the thickness of the part considered for which Level A Limits are specified.

Design Mechanical Loads – The specified Design Mechanical Loads are in accordance with NCA-2142.4. The specified Design Mechanical Loads are selected so that when combined with the effects of Design Pressure, they represent the most severe coincident loadings for which the Level A Service Limits on primary stress are applicable.

3.9.3.6.3 Service Conditions

The Service Conditions are established in accordance with NB-3113, NCD-3113, NE-3113, NF-3113, or NG-3113, as applicable.

Each service condition to which the components may be subjected is classified in accordance with Service Limits designated in the component design specifications in such detail as to provide a complete basis for design, construction, and inspection. The loadings are taken into account in accordance with NB-3111, NCD-3111, NF-3111 or NG-3111, as applicable.

For ASME Class 1 components, the requirements of (1) and (2) below apply:

1. Level B Conditions – The estimated duration of service conditions for which Level B Limits are specified and included in the design specifications.

2. Level C Conditions – The total number of postulated occurrences for all specified service conditions for which Level C Limits are specified are limited to no more than twenty-five stress cycles having an Sa value greater than that for 10^6 cycles from the applicable fatigue design curves of ASME BPVC Section III, Mandatory Appendix I.

When the Component Design Specification requires computations to demonstrate compliance with specified Service Limits, the Component Design Specification provides information from which Service Loadings can be identified (pressure, temperature, mechanical loads, cycles, or transients).

3.9.3.6.4 Test Loadings

Test Pressure – The specified internal and external test pressures are as required by ASME BPVC, Section III.

Test Loads – Loads due to other types of required tests are included as required by ASME BPVC, Section III.

Test Temperature – Test temperature is defined to ensure that thermal effects are considered in test loads.

3.9.3.7 Loading Phenomena

Subsection 3.9.3.7 describes the types of load phenomena, which are considered for components, as applicable. Consists of pressure, dead weight, fluid reaction, prestress, fluid flow (including FIV when applicable) and other loads due to moving parts within a component or system.

“N” loads in Table 3.9-3 include Thermal Effects. Individual component specifications may elect to break out the thermal effects loads separately for the sake of clarity, if desired.

Thermal loads are included in this category for each service level, which are thermally induced loads caused by both steady state and transient operating conditions. The thermal anchor displacement loads are due to the anchor displacements (end motion) caused by thermal expansion, or pressure dilation, or other dynamic loads at anchor boundary locations.

3.9.3.7.1 Flow Induced Vibration

Flow of fluids past objects creates local pressure disturbances, which exert forces on the object. These forces can cause dynamic responses depending on the forcing function and dynamic characteristics of the object. Flow induced vibrations have been noted in nuclear power plant systems, which produce vortex shedding (e.g., heat exchangers), pump (reciprocating or centrifugal), and thermodynamic instability conditions. Mechanical systems and equipment are reviewed for potential flow induced vibration mechanisms, evaluating all modes of system operation including both normal and abnormal conditions.

Flow induced vibration loads may be associated with Service Level A for those structures (e.g., reactor internals) where the loads exist during normal operation. For flow induced vibration loads associated with transients that are not considered part of normal operation, the flow induced vibration loads are evaluated as part of the alternative service level.

Consistent with SIL No. 682, “Flow Induced Vibration Load,” (Reference 3.9-20), the RPV component design considers the loads due to normal operation vibration (flow induced vibration) without combination of other primary loads.

Vortex Shedding

Vortex shedding occurs at certain fluid velocities when a fluid flows past objects. The vibration cannot be eliminated, but it can usually be controlled. It is important that these cases consider all potential modes of component operation. Vortex shedding hydrodynamic mass effects are considered. Other components susceptible to flow induced vibration are pressure, flow, and temperature sensors, which encroach upon the flow stream.

Pressure Fluctuations

Pressure fluctuations in a vapor or gas-state fluid (e.g., steam) occur due to flow past branch piping connections and branch connected components (e.g., safety valve “bell chamber” resonance), flow through short radius elbow fittings that induce flow separation effects, flow passing through valve chambers, flow past sharp-edged in-line pipe components (e.g., orifices,

weld joint backing rings, valve seat rings), or two or more individual flows entering a common header or drum that generates an acoustic response. These various flow disturbances generate acoustic waves that can travel forward and backward in a piping system. If of sufficient strength and at a component's susceptible frequency, these acoustic resonances can cause cyclic fatigue and result in component failure.

Pumps create pressure fluctuations in a fluid system. In most system designs, these fluctuations are insignificant. However, the possibility exists that these fluctuations, coupled with unintentional but improper system or component structural characteristics, can cause resonant vibrational response in the system or component. Component structural characteristics are designed to assure a resonance value sufficiently high to avoid excitation by evaluated system fluid fluctuations. Pressure attenuation devices are used as applicable to significantly reduce the effects of this phenomenon.

Thermodynamic Instability

Under certain system design features and operating modes, fluid dynamic forces can be generated, which create large pressure variations. These have been noted in certain feedwater systems where a relatively cold fluid layer is in contact with a relatively hot steam region; under certain operating modes significant water-hammer-type phenomena have occurred causing a breach of the pressure-retaining boundary.

3.9.3.7.2 Rapid Valve Closure or Opening

Extremely rapid valve closure or opening in a fluid system can create large pressure waves which can propagate through a piping system and into connected components. This rapid motion could be caused by operating characteristics of the valve (e.g., stiffness of diaphragm in pneumatic operators), or the fluid flow forces acting on the valve parts during all modes of operations. Rapid valve closure or opening is defined as an AOO.

For example, Turbine Stop Valve (TSV) closure may be identified as being capable of generating large pressure waves which could cause significant dynamic response. Prior to TSV closure, saturated steam flows through Main System (MS) piping at nuclear boiler rated pressure and mass rate. Steam flow to the turbine comes to a stop at the instant the turbine-stop valve closes. The flow of steam travels in the MS line through the vessel nozzle and into the vessel. This results in a compressive acoustic load and a steam impingement load on the steam dryer outer hood. Additionally, repeated reflections of the compression wave in the MS line generate time-varying forces in the MS piping. SSCs in the Reactor Building, Steam Tunnel and Turbine Building may be affected. TSV closure is conservatively evaluated as an AOO.

3.9.3.7.3 Isolation Condenser Operation

The thermal effects associated with operation of ICS and the loads such as pressure resulting from operation of ICS are considered. Loads associated with the breaks of ICS high pressure lines in the pool are considered. The major loads imposed on ICS result from:

- Sudden reactor isolation at power operating conditions

- During station blackout (i.e., unavailability of all alternate current power)
- Failure to SCRAM
- LOCA

3.9.3.7.4 Failures of High-Energy Fluid System Piping

The effects of postulated pipe breaks in high-energy fluid systems as well as measures used to protect SSCs are defined in Subsection 3.6.

3.9.3.7.5 Failures of Moderate-Energy Fluid System Piping

The effects of postulated pipe cracks in moderate-energy fluid systems as well as measures used to protect SSCs are defined in Subsection 3.6.

3.9.3.7.6 Fuel Lift Loads

Fuel lift is the postulated process under which a combination of vertical motion of the RPV support, scram uplift forces on the fuel assemblies and vertical hydraulic forces result in fuel assemblies lifting off from their seating surfaces on the fuel support. The reaction load of the fuel on the core support structures is considered.

3.9.3.8 Safety Class Equipment and Safety Category Functional Criteria

For any normal or upset service level, the component or support must withstand these loadings without damage requiring repair.

For any emergency or faulted service level, these sets of limits promote large (Service Level C) or gross (Service Level D) general deformations with some consequent loss of dimensional stability and damage requiring repair, that may require removal of the component or support from service.

3.9.3.9 Reactor Vessel Assembly

The reactor vessel assembly includes: The RPV pressure boundary out to and including the nozzles, the RIVs, and the housings for FMCRD and nuclear instrumentations. The RPV assembly is ASME Class 1.

The stress analysis is performed on the RPV for various plant operating conditions (including faulted conditions) by using elastic methods. Load combinations and acceptance criteria for reactor internals are provided in Table 3.9-3.

The RPV internals are listed in Table 3A-1.

3.9.3.10 Main Steam Piping

The Main Steam (MS) piping trains extending from the outboard Main Steam Reactor Isolation Valve (MSRIV) up to the Seismic Interface Restraints (SIR) that are outboard of the Main Steam Containment Isolation Valves (MSCIV) are designed and constructed in accordance with the

ASME BPVC, Section III, Subsection NCD requirements for Class 2 components. Stresses are calculated on an elastic basis for each service level and evaluated in accordance with NCD-3600. Table 3.12-2 shows the specific load combinations and acceptance criteria for Class 2 piping that apply to this piping.

The SIRs are designed to ASME BPVC, Section III, Subsection NF. The MS system piping extending from the outboard SIR to the TSV is constructed in accordance with the ASME B31.1 criteria.

3.9.3.11 Other Components

3.9.3.11.1 Isolation Condenser System

The ICS piping inside the containment is designed and constructed in accordance with the ASME BPVC, Section III, Class 1 requirements. The Isolation Condenser and piping outside containment are designed and constructed in accordance with ASME BPVC, Section III Class 1 requirements.

3.9.3.11.2 Reactor Water Cleanup System Heat Exchangers

The Reactor Water Cleanup System (CUW) heat exchanger does not perform any Safety Category 1 functions. The heat exchanger is Non-Seismic equipment. The ASME BPVC, Section VIII, Division 1, “Rules for Construction of Pressure Vessels,” (Reference 3.9-17) requirements are used in the design and construction of the CUW heat exchanger.

3.9.3.11.3 Shutdown Cooling System Pump and Heat Exchangers

The Shutdown Cooling System (SDC) heat exchangers do not perform any Safety Category 1 functions. The pumps and heat exchangers are Non-Seismic equipment. The ASME BPVC, Section VIII, Division 1 requirements are used in the design and construction of the SDC pump and heat exchanger.

3.9.3.11.4 ASME Class 2 and 3 Vessels

ASME Class 2 and 3 vessels are constructed in accordance with ASME BPVC, Section III.

3.9.3.11.5 ASME Class 1, 2, and 3 Valves

ASME Class 1, 2, and 3 valves are constructed in accordance with ASME BPVC, Section III.

All valves and their extended structures are designed to withstand the accelerations due to seismic and other RBV loads. Refer to Subsection 3.9.3.12 for additional information on valve operational readiness.

3.9.3.11.6 ASME Class 1, 2, and 3 Piping

ASME Class 1, 2 and 3 piping is constructed in accordance with the ASME BPVC, Section III. For ASME Class 1 piping, stresses are calculated on an elastic basis and evaluated in accordance with NB-3600 and fatigue usage is determined. For ASME Class 2 and 3 piping,

stresses are calculated on an elastic basis and evaluated in accordance with NCD-3600. Tables 3.12-1 and 3.12-2 provide the specific load combinations and acceptance criteria for ASME Class 1, 2, and 3 piping systems.

3.9.3.12 Valve Operational Readiness

SC1 valves considers the qualification guidance provided in ASME QME-1 for their qualification program. Sections 3.10 and 3.11 provide details on the seismic and environmental qualification of valves.

The requirements in this section apply to SC1 valves and their associated Safety Category 1 functions. Functional qualification does not include independent verification and validation testing of software. Although functional qualification by testing or analysis is not required for SC2 and SC3 valves, SC2 and SC3 valves are designed to be capable of performing their required function(s) under the expected operating and environmental conditions for the required mission time.

3.9.3.13 Design of Pressure Relief Devices

The RCS does not utilize safety or relief valves for overpressure relief. During normal operation, the MS flow to the turbine is throttled to control system pressure. Section 6.3 describes the method of RPV overpressure relief that is based on NEDC-33910P-A.

3.9.3.14 Component Supports

The establishment of the design/service loadings and limits is in accordance with ASME BPVC, Section III, Subsection NF. These loadings and stress limits apply to the structural integrity of components and supports when subjected to combinations of loadings derived from plant and system operating conditions and postulated plant events.

ASME BPVC, Section III component supports are designed, manufactured, installed, and tested in accordance with all applicable codes and standards. The building structure component supports (connecting the NF support boundary component to the existing building structure) are designed as specified in Section 3.8.

The design of bolts for component supports is specified in ASME BPVC, Section III, Subsection NF. Stress limits for bolts are given in NF-3225. The rules and stress limits which must be satisfied are those given in NF-3324.6 multiplied by the appropriate stress limit factor for the particular service loading level and stress category specified in Table NF-3225.2-1.

3.9.3.15 Piping Supports

Supports and their attachments for ASME BPVC, Section III Class 1, 2, and 3 piping are designed in accordance with Subsection NF up to the interface of the building structure, with jurisdictional boundaries as defined by Subsection NF. Pipe supports include hangers, snubbers, struts, spring hangers, frames, energy absorbers and limit stops.

The design of supports for non-BPVC piping satisfies the requirements of ASME B31.1 and ASME B31.3.

3.9.3.16 Reactor Pressure Vessel Stabilizer

The RPV stabilizer is designed as an SC1 linear type component support in accordance with the requirements of ASME BPVC, Section III, Subsection NF. The main function of the stabilizers is to provide horizontal support to limit vessel motion by transferring load from the vessel to the adjacent civil structure. Upper and lower vessel stabilizers function independently, depending on the direction of vessel motion due to an applied dynamic force, but horizontally and vertically parallel stabilizers act with combined resistance against vessel motion. The design loading conditions and stress criteria meet the ASME BPVC, Section III stresses in the critical support areas for various plant operating conditions.

3.9.4 Control Rod Drive System

The CRD system is described in Section 4.6. The CRD system is an SC1 system and portions of the CRD system are a part of the RCPB, the system is designed, fabricated, and tested to quality standards commensurate with the safety category functions that are performed.

The CRD system includes the FMCRD mechanisms, the HCU assemblies, and the CRD hydraulic subsystem. The system extends inside the RPV to the coupling interface with the control rod blades.

The BWRX-300 design complies with the relevant requirements of the following 10 CFR 50 Appendix A and 10 CFR 50.55a regulations.

The CRD system complies with the following GDC, which have plant-wide applicability, as discussed in Section 3.1:

GDC 1 – Quality standards and records

GDC 2 – Design bases for protection against natural phenomena

The following GDC have aspects specific to the CRD system design and compliance is addressed as follows:

GDC 14 – Reactor coolant pressure boundary, as it relates to the CRD system, requires that the RCPB portion of the CRD system be designed, constructed, and tested for the extremely low probability of leakage or gross rupture. The design involves meeting the ASME BPVC, Section III, Subsection NB acceptance criteria utilizing load combinations in Table 3.9-3, including transient plant duty cycles in Table 3.9-2 for the 60-year life period to assure minimal abnormal leakage.

GDC 26 – Reactivity control system redundancy and capability, as it relates to the CRD system, requires that the control rods are used in the reactivity control system, preferably including a positive means for inserting the rods, and shall be capable of reliably controlling reactivity changes to assure that under conditions of normal operation, including AOOs, and with appropriate margin for malfunctions such as stuck rods, SAFDLs are not exceeded.

GDC 27 – Combined reactivity control systems capability, as it relates to the CRD system, requires that the reactivity control systems be designed to reliably control reactivity changes to assure that under postulated accident conditions and with appropriate margin for stuck rods the capability to cool the core is maintained.

GDC 29 – Protection against anticipated operational occurrences, as it relates to the CRD system requires that the CRD system, in conjunction with reactor protection systems, be designed to assure an extremely high probability of accomplishing its safety functions in the event of AOOs. The design of the CRD system to ASME BPVC, Section III Service Level A through D and test conditions as outlined in Table 3.9-3 assures accomplishment of safety functions in the event of an AOO, thus complying with GDC 29.

Additional Information on GDC compliance is found in Section 3.1.

3.9.4.1 Descriptive Information on Control Rod Drive System

Descriptive information on the FMCRDs as well as the entire CRD system is contained in Section 4.6.

3.9.4.2 Applicable Control Rod Drive System Design Specification

The CRD system, which is designed to meet the functional design criteria outlined in Section 4.6 consists of the following:

- Electro-hydraulic FMCRD mechanisms
- Hydraulic Control Unit
- CRD Hydraulic Subsystem

The subcomponents of the FMCRD forming part of the RCPB are designed according to ASME BPVC, Section III, Subsection NB requirements.

The quality group classification of the components of the CRD system is listed in Table 3A-1 and are designed to the codes and standards in accordance with their individual quality groups.

Pertinent aspects of the design and qualification of the CRD system components are discussed in the following locations: transients in Subsection 3.9.1.1, Subsection 3.9.3.6, and Subsection 3.9.3.7, faulted conditions in Subsection 3.9.1.4.1 and Subsection 3.9.1.4.2.

3.9.4.3 Design Loads, Stress Limits, and Allowable Deformations

The ASME BPVC, Section III, Subsection NB components of the CRD system are evaluated analytically, and the design loading conditions, and stress criteria are given in Table 3.9-3.

3.9.4.4 Control Rod Drive Performance Assurance Program

The assurance of the CRDM RCPB components to perform throughout the 60-year design life of the system is confirmed by the ASME Class 1 design report required by ASME BPVC, Section III, Subsection NB.

Refer to Section 4.6 for required tests to assure CRD operability.

3.9.5 Reactor Pressure Vessel Internals

Refer to Subsection 4.1.2 and Figure 4.1-1 for a detailed description, design, and function.

The Reactor Pressure Vessel Internals comply with the following GDC, which have plant-wide applicability, as discussed in Section 3.1:

GDC 1 – Quality standards and records (SC1, SC2, and SC3)

GDC 2 – Design bases for protection against natural phenomena (SC1)

GDC 4 – Environmental and dynamic design bases

The following GDC have aspects specific to the BWRX-300 design and compliance is addressed as follows:

GDC 10 – Reactor Design. This GDC requires that reactor internals be designed with appropriate margin to assure that specified acceptable fuel design limits are not exceeded during any condition of normal operation, including the effects of AOOs. The reactor internals consist of pressure boundary, non-pressure boundary components, and support structures that are designed to maintain structural integrity per Subsection 3.9.1, Subsection 3.9.2, and Subsection 3.9.3, and maintain Specified Acceptable Fuel Design Limits (SAFDL) as discussed in Section 4.3.

Additional Information on GDC compliance is found in Section 3.1.

3.9.6 Functional Design, Qualification, and Inservice Testing Programs for Pumps, Valves, and Dynamic Restraints

Sections 3.10 and 3.11 provide the method for qualification of mechanical equipment. The qualification involves both determining component functionality while maintaining structural integrity under seismic, dynamic, and environmental conditions. Seismic testing of components is performed as well as use of analytical methods.

The Functional Design, Qualification, and Inservice Testing Programs for Pumps, Valves, and Dynamic Restraints complies with the following GDC, which have plant-wide applicability, as discussed in Section 3.1:

GDC 1 – Quality standards and records

GDC 2 – Design bases for protection against natural phenomena

GDC 4 – Environmental and dynamic design bases

The BWRX-300 design complies with the relevant requirements of the following 10 CFR 50 Appendices A and 10CFR 50.55a regulations as stated below:

GDC 14 – Reactor coolant pressure boundary, as it relates to designing, fabricating, erecting, and testing pumps, valves, and dynamic restraints that form the RCPB so as to have an extremely low probability of abnormal leakage, rapidly propagating failure, and gross rupture designed in accordance with Subsection 3.9.1, Subsection 3.9.2, Subsection 3.9.3, and Section 3.10, therefore complying with the requirements of GDC 2 for the 60-year life period to assure minimal abnormal leakage.

GDC 15 – Reactor coolant system design, as it relates to pumps, valves, and dynamic restraints that form the RCS and associated auxiliary, control, and protection systems being designed with sufficient margin to ensure that the design conditions of the RCPB are not exceeded during any condition of normal operation, including AOO and DBA event sequences designed in accordance with Subsection 3.9.1, Subsection 3.9.2, Subsection 3.9.3, and Section 3.10, therefore complying with the requirements of GDC 15.

GDC 37 – Testing of emergency core cooling system, as it relates to designing the ECCS to permit periodic pressure and functional testing to ensure the leak tight integrity and operability and performance of its active components. The ECCS design incorporates adequate space and connections to allow for periodic pressure and functional testing. Design completion will occur during FSAR phase.

GDC 40 – Testing of containment heat removal system, as it relates to designing periodic pressure and functional testing of the passive containment cooling system to ensure the leak tight integrity and operability and performance of its active components. The passive containment cooling system design incorporates adequate space and connections to allow for periodic pressure and functional testing. Design completion will occur during FSAR phase.

GDC 43 – Testing of containment atmosphere cleanup systems, as it relates to designing the containment atmospheric cleanup systems to permit periodic pressure and functional testing to ensure the leak tight integrity and the operability and performance of the active components. The BWRX-300 containment atmosphere system is an inerted system design that incorporates adequate space and connections to allow for periodic pressure and functional testing as described in Subsection 9.3.6. Design completion will occur during FSAR phase.

GDC 46 – Testing of cooling water system, as it relates to designing the cooling water system to allow periodic pressure and functional testing to ensure the leak tight integrity and operability and performance of the active components. The cooling water system design incorporates adequate space and connections to allow for periodic pressure and functional testing. Design completion will occur during FSAR phase.

GDC 54 – Piping systems penetrating containment, as it relates to designing piping systems penetrating containment with the capability to test periodically the operability of the isolation valves and associated apparatus and determine valve leakage acceptability. The piping system containment penetration design incorporates adequate space and connections to allow for periodic pressure and functional testing. Design completion will occur during FSAR phase.

Additional Information on GDC compliance is found in Section 3.1.

Appendix B to 10 CFR Part 50, as it relates to quality assurance in the design, fabrication, construction, testing, and records control of SC1 pumps, valves, and dynamic restraints. Compliance with 10 CFR 50 Appendix B will occur during FSAR phase during design development.

IST Programs are developed for required operability and functional tests for components as described below:

- Necessary instrumentation, test connections, flow instruments, or other provisions that are required to fully comply with the requirements are included.
- Valves required to be seat leakage tested have provisions for testing the leak-tightness of the valves in the direction in which the valves are required to be leak tight except as allowed in 10 CFR 50 Appendix J or ASME OM Code, “Operation and Maintenance of Nuclear Power Plants,” ISTC-3630(b) (Reference 3.9-11).
- ASME OM Code, Nonmandatory Appendix M provides design guidance of system and component testing.

The IST Program includes periodic tests and inspections that demonstrate the operational readiness of SC1 components, pumps, valves, and snubbers (dynamic restraints) and their capability to perform their safety category functions. Table 3.9-4 provides a preliminary list of active valves. Active valves were identified from the perspective of their normal position and safety position.

The IST Program is based on the requirements of ASME OM Code as incorporated by reference in 10 CFR 50.55a as follows:

- The specific ASME OM Code requirements for functional testing of pumps are found in Subsection ISTF for plants designed after 2000.
- Requirements for IST of valves are found in Subsection ISTC and Mandatory Appendices III (motor-operated valves) and IV (air-operated valves).
- Requirements for dynamic restraints (snubbers) are found in Subsection ISTD.
- Requirements for IST of pressure relief devices are found in Mandatory Appendix I.

- Requirements for Check Valve Condition Monitoring are found in Mandatory Appendix II.
- General requirements for IST are found in Subsection ISTA.

IST of Pumps

The BWRX-300 design does not require the use of pumps to perform a specific function in shutting down the reactor to the safe shutdown condition, maintaining the safe shutdown condition, or mitigating the consequences of an accident. Therefore, there are no pumps required to be included in the IST Program.

IST of Valves

Certain ASME BPVC Classes 1, 2, and 3 valves and pressure relief devices are subject to IST in accordance with ASME OM Code, Subsection ISTC or Appendix I, including the general requirements in Subsection ISTA. IST of valves assesses operational readiness, including actuating and position-indicating systems. The valves that are subject to IST include those valves that perform a specific function in shutting down the reactor to a safe shutdown condition, maintaining a safe shutdown condition, or mitigating the consequences of an accident. In addition, pressure relief devices used for protecting systems or portions of systems that perform a function in shutting down the reactor to a safe shutdown condition, maintaining a safe shutdown condition, or mitigating the consequences of an accident, are subject to IST.

ASME OM Code, Table ISTC-3500-1 requires the following four basic valve tests:

1. Exercise tests
2. Seat leakage tests
3. Remote position indicator tests
4. Special tests (e.g., fail-safe tests, explosive valve tests, rupture disk tests)

Valve Categories

Non-exempt ASME BPVC Class 1, 2, and 3 valves are categorized in accordance with ASME OM Code, ISTC-1300 (2) as follows:

1. Category A – valves for which seat leakage is limited to a specific maximum amount in the closed position for fulfillment of their required function(s)
2. Category B – valves for which seat leakage in the closed position is inconsequential for fulfillment of the required function(s)
3. Category C – valves that are self-actuating in response to some system characteristic, such as pressure (relief valve) or flow direction (check valve) for fulfillment of the required function(s)

4. Category D – valves that are actuated by an energy source capable of only one operation, such as rupture disks or explosively actuated valves

When more than one distinguishing category characteristic is applicable, all requirements of each of the individual categories are applicable, although duplication or repetition of common testing requirements is not necessary.

Valve Exercise Tests

Active Category A valves, Category B valves, and Category C check valves are exercised periodically, except for self-actuated safety and relief valves. The ASME OM Code specifies a quarterly valve exercise frequency for all valves except power-operated safety and relief valves, which are required to be tested once per fuel cycle. Manual valve exercise tests are discussed in ISTC-3540. Where it is not practicable to exercise a valve during normal power operation, the valve exercise test is deferred to either cold shutdown or refueling outages. In some cases, quarterly stroke testing is deferred to refueling outages or cold shutdown. The bases for deferral are consistent with ISTC-3500. Where practical, the BWRX-300 is designed to accommodate quarterly stroke testing.

During valve exercise tests, the necessary valve obturator movement is determined by exercising the valve while observing an appropriate direct indicator, such as indicating lights that signal the required changes of obturator position, or by observing other evidence or positive means, such as changes in system pressure, flow, level, or temperature that reflect change of obturator position.

Check valve exercise tests use direct observation or other positive means (ISTC-5221(a)) for verification of valve obturator position by performing both an open and a close test.

Active and passive Category A containment isolation valves are tested to verify seat leakage is within limits in accordance with 10 CFR 50 Appendix J. Frequencies of containment isolation valve seat leakage tests are in accordance with the 10 CFR 50 Appendix J requirements.

Other Category A valves are required to be seat leakage tested at least once every two years as specified by ISTC-3630.

Check valves that have seat leakage requirement are leak tested in accordance with ISTC-3600.

The USNRC allows licensees to apply the ASME OM Code Cases listed in RG 1.192, as incorporated by reference in 10 CFR 50.55a(a)(3)(iii), without prior USNRC approval, subject to the conditions in 10 CFR 50.55a(b)(6).

Relief from the testing requirements of the ASME OM Code is requested when compliance with requirements of the ASME OM Code is not practical. In such cases, specific information is provided which identifies the impractical code requirement, justification for the relief request, and the testing method to be used as an alternative. Demonstration of the impracticality of the testing required by the ASME OM Code, and justification for alternative testing proposed, are provided.

The BWRX-300 IST Program does not invoke the use of any ASME code cases for valve IST.

IST of Snubbers

- At this time, no snubbers are included in the BWRX-300 design. This could change as civil design matures. The following requirements are not all inclusive but provide IST requirements applicable to BWRX-300 if snubbers are incorporated at a future date.
- Preservice operability testing is to be performed on all snubbers. Tests verify the parameters described in ISTD-5131.
- Snubbers are tested at a load sufficient to verify the test parameters specified in ISTD-5131. Any snubbers that fail the preservice operational readiness test are evaluated for causes of failure. If a design deficiency is found, it is corrected, adjusted, repaired, or replaced. Failed snubbers are tested to meet the requirements in ISTD-5131.
- Snubber operational readiness checks verify the parameters described in ISTD-5210.
- Snubbers are tested at a load sufficient to verify the test parameters specified in ISTD-5100, ISTD-5200, and ISTD-5300, or ISTD-5400 and ISTD-5500.
- Snubbers are tested for operational readiness during each fuel cycle as defined in ISTD-5240. Test campaigns are required to be in accordance with a specified sampling plan as defined in ISTD-5260.

The snubbers IST sample is selected using one of the following two sample plans:

- 10% testing sample plan
- 37 testing sample plan (test 37 snubbers)

For more detailed requirements on testing sample plans, refer to ISTD-5300 and ISTD-5400.

- Snubbers preservice and IST, including their interval and percent of sample lot size requirements, are performed in accordance with ISTD-5131.
- Snubbers testing documentation necessary to verify the results of the preservice and IST Program is in accordance with the requirements in ISTD-9000.

3.9.7 Risk Informed Inservice Testing

This section will be addressed in the FSAR.

3.9.8 Risk Informed Inservice Inspection of Piping

This section will be addressed in the FSAR.

Table 3.9-1 Design Condition Definition

Service Condition	Typical ASME Service Level for Components	Plant State or Estimated Frequency Occurrence of PIE Used for Categorization
Normal	A	Planned Operation
Upset	B	AOO
Emergency	C	DBA of low frequency
Faulted	D	DBA of very low frequency
DEC	N/A; best-estimate methods may be applied	Event-specific basis (Note 1)

Note:

1. Events with a probability of occurrence in the DEC range (less than 1E-05 per reactor-year) are addressed on an event-specific basis.

Table 3.9-2 Cycles of Events

Event Number	Description	Design Basis Number of Cycles	Service Condition
1	Bolt-up	72	Normal
2A	Hydrostatic Testing	6	Normal
2B	System Leakage Test	144	Normal
3	Startup	200	Normal
4	Turbine Rolland Increase to Rated Power	200	Normal
5	Daily Load Reduction and Recovery	18,738	Normal
6	Rod Sequence/Pattern Change	60	Normal
7A	Inadvertent Isolation Condenser Initiation – One Train (Power Operation)	8	Upset
7B	Inadvertent Isolation Condenser Initiation – One Train (Hot Shutdown)	2	Upset
8	Feedwater Flow Increase	19	Upset
9	Turbine Valve Fail Open	25	Upset
10	Loss of Feedwater Heaters – Partial	59	Upset
11	Turbine Generator Trip, Other Scrams with Bypass Flow	67	Upset
12A	Scrams Without Bypass without Feedwater	37	Upset
12B	Scrams Without Bypass with Feedwater	30	Upset
13	Rated Power Operation	N/A	Normal
14	Reduction to 0% Power	200	Normal
15	Hot Shutdown	200	Normal

3.10 Seismic and Dynamic Qualification of Mechanical and Electrical Equipment

The BWRX-300 Seismic Category I mechanical and electrical equipment (including Instrumentation and Control (I&C) components) are designed to withstand the effects of earthquakes (i.e., Seismic Category I requirements), and other accident-related dynamic loadings.

Mechanical equipment consists of pumps, valves, valve operators, vessels, and piping whose function is required to ensure safe operation or safe shutdown. Electrical equipment consists of all electrical power and I&C equipment, which includes all analog (non-digital) and digital I&C components. Computer-based I&C equipment is a subset of digital I&C components. Examples of electrical equipment are battery and battery racks, instrument and instrument racks, control consoles, electrical cabinets, electrical panels, valve operator motors, solenoid valves, pressure switches, relays, level transmitters, electrical penetrations, and pump and fan motors.

Structures, Systems, and Components (SSCs) that are credited to remain functional during or after a seismic event are Seismic Category I. SSCs whose failure during a seismic event could adversely affect the ability of Seismic Category I SSCs to accomplish their fundamental safety functions are classified as Seismic Category II. A list of preliminary BWRX-300 SSCs classification, their location, seismic category, and quality group is provided in Table 3A-1.

The BWRX-300 design discussed in Section 3.10 complies with the following GDC, which have plant-wide applicability, as discussed in Section 3.1:

GDC 1 – Quality standards and records

GDC 2 – Design bases for protection against natural phenomena

GDC 4 – Environmental and dynamic design bases

The following GDC have aspects specific to Section 3.10 and compliance is addressed as follows:

GDC 14 – Reactor coolant pressure boundary. Section 3.9.2 addresses dynamic testing of components of the Reactor Coolant Pressure Boundary (RCPB) to ensure it can withstand the applicable design-basis seismic and dynamic loads in combination with other environmental and natural phenomena loads without leakage, rapidly propagating failure, or gross rupture. Accordingly, the requirements of GDC 14 are met.

GDC 30 – Quality of reactor coolant pressure boundary. The methods of test and analysis employed to ensure the operability of mechanical and electrical equipment are based on International Electrotechnical Commission (IEC)/Institute of Electrical and Electronics Engineers (IEEE) 60980-344 “Nuclear Facilities – Equipment Important to Safety – Seismic Qualification,” (Reference 3.10-1). RG 1.100 endorses IEEE-344-2013. The BWRX-300 design utilizes IEC/IEEE 60980-344-2020. The additional guidance provided in RG 1.100 is used to identify individual components of the RCPB demonstrating through testing and analysis, or a

combination of both, that a given component will not fail as a result of any combination of loadings for which it is qualified. This ensures that components are tested to the highest quality standards practical. Accordingly, the requirements of GDC 30 are met.

Additional Information on GDC compliance is found in Section 3.1.

Seismic design and design of Seismic Category I SSCs are addressed in Section 3.7 and Section 3.8. General design aspects of mechanical systems and components are addressed in Section 3.9.

3.10.1 Seismic and Dynamic Qualification Criteria

A determination of the criteria for seismic and dynamic qualification is dependent on the type of equipment to qualify mechanical, electrical, and/or I&C, and the required seismic and dynamic inputs necessary to demonstrate structural and/or functional integrity. The criteria is provided in the following sections.

3.10.1.1 Qualification Standards

The guidance provided in the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code (BPVC) Section III, Division 1, “Rules for Construction of Nuclear Facility Components,” (Reference 3.10-2) is followed in the design of Safety Class 1 (SC1) mechanical equipment to achieve the structural integrity of pressure boundary components. SC1 valves consider the qualification guidance provided in ASME QME-1, “Qualification of Active Mechanical Equipment Used in Nuclear Facilities,” (Reference 3.10-3) for their qualification program.

Seismic and dynamic qualification of mechanical and electrical equipment and associated supports are considered for testing, analysis, or a combination of testing and analysis in accordance with IEC/IEEE 60980-344 in accordance with RG 1.100.

3.10.1.1.1 Qualification by Actual Seismic Experience

IEC/IEEE 60980-344 provides experience based seismic qualification methodology and is utilized as appropriate. In addition, ASME QME-1 seismic experience may be utilized as appropriate. The information includes:

1. The credibility and completeness of compilation of the earthquake experience database for the seismic qualification of electrical equipment
2. The inclusion and exclusion rules for electrical equipment in the experience database
3. The justification used to demonstrate the similarity among the member items in a reference equipment class
4. The justification used to demonstrate the similarity between electrical equipment in the experience database and equipment in the BWRX-300 for seismic qualification purposes

5. The justification used to demonstrate the functionality of equipment and the member items in a reference equipment class during and after a seismic event.

3.10.1.1.2 Qualification by Similarity

Qualification by similarity for Seismic Category I and II equipment is based on operating experience of similar equipment or to qualify multiple similar pieces of equipment by testing and/or analyzing only one of the pieces of equipment. When extrapolation of data is made from similar equipment, a description of the differences between the equipment items involved is required. Justification that the differences do not degrade the environmental and/or seismic adequacy below acceptable limits and any additional supporting data is included.

Test results can be extrapolated for dynamic loading conditions in excess of, or different from, previous tests on a piece of equipment if the test results are in sufficient detail to allow an adequate dynamic model of the equipment to be generated. The model provides the capability of predicting failure under the increased or different dynamic load excitation. IEC/IEEE 60980-344 defines the analytical method utilized in similarity qualification.

3.10.1.1.3 Functional Qualification of Active Mechanical Equipment

The seismic qualification of active mechanical equipment is performed considering the methods and requirements specified in ASME QME-1.

3.10.1.2 Qualification Program

The equipment qualification program follows the requirements provided in IEC/IEEE 60780-323, “Nuclear Facilities – Electrical Equipment Important to Safety – Qualification,” (Reference 3.10-4) and is used to determine the overall equipment qualification test plan, including Environmental Qualification (EQ) provided in Section 3.11. The program meets the qualification criteria contained in IEC/IEEE 60980-344 that includes seismic and dynamic mechanical and electrical equipment qualification.

3.10.1.3 Seismic Qualification Report

The seismic qualification report follows the requirements that are defined in IEC/IEEE 60980-344 and is specific to the Seismic Category I electrical and mechanical equipment and associated supports to be qualified.

3.10.2 Methods and Procedures for Qualifying Mechanical and Electrical Equipment

3.10.2.1 Seismic Input Motion

Dynamic load conditions are simulated by testing using independent, random multi-frequency input or single frequency input motion (within equipment capability) over the frequency range of interest.

Acceptable justification for use of single frequency input includes, but is not limited to:

1. The characteristics of the required input motion are dominated by one frequency.

2. The anticipated response of the equipment is adequately represented by one mode.

3. The input has sufficient intensity and duration to excite all modes to the required magnitude so that the testing response spectra envelop the corresponding response spectra of the individual modes.

4. The time phasing of the inputs in the vertical or horizontal directions is such that a purely rectilinear resultant input is avoided.

The actual input motion used during testing, for both multi and single frequency, envelops the applicable input motion (floor, wall, response, etc.) at the location(s) of the equipment under test.

When the equipment is qualified by dynamic test, the In-Structure Response Spectra (ISRS) or time histories are used in determining required response spectra of input motion used for the test.

When both test and analysis are defined as acceptable methods, the deciding factors considered (as applicable) for choosing between tests or analysis includes:

- Magnitude of accelerations and frequency content of seismic and Reactor Building Vibration (RBV) dynamic loadings
- Environmental conditions associated with the dynamic loadings
- Nature of the function(s) required for a seismic event
- Size and complexity of the equipment
- Dynamic characteristics of expected failure modes (structural or functional)
- Partial test data upon which to base the analysis

Tests or analyses of assemblies are preferable to tests or analyses on separate components (e.g., a motor and a pump, including the coupling and other appurtenances, should be tested, or analyzed as an assembly). The replacement parts may be tested separately, if applicable.

Equipment that has been previously qualified by means of tests and analyses equivalent to those required for the current qualification program are used if proper documentation of such tests and analyses is available.

3.10.2.2 Qualification by Testing

Seismic qualification of mechanical and electrical equipment including I&C by testing is performed in accordance with the requirements of IEC/IEEE 60980-344.

3.10.2.2.1 Interface Requirements

Intervening structures or components (such as interconnecting cables, bus ducts, conduits) that serve as interfaces between the equipment to be qualified and that are supplied by others, are not qualified as part of the seismic equipment qualification program. When applicable, accelerations and frequency content at locations of interfaces with interconnecting cables, bus ducts, and conduits are determined and documented. This information is specified in the form of interface criteria.

3.10.2.2.2 Test Methods

The test methods presented in IEC/IEEE 60980-344 provide acceptable types of testing dependent on the type of motion selected based on the expected vibration environment and technical requirements of the specific application. Past testing demonstrates that BWRX-300 Seismic Category I electrical equipment has critical damping ratios equal to or less than 5%. Hence, Required Response Spectra (RRS) at 5% or less critical damping ratio are developed as input to the equipment base.

The preferred method for seismic testing is to use triaxial, multi-frequency testing. However, if justified, biaxial and single-axis testing is acceptable. If biaxial testing is justified to be used, then each test is performed in two steps, where the first step is to apply the input motion to both the vertical and horizontal axis simultaneously. For the second step, the test specimen is rotated 90 degrees in the horizontal plane, and a second test is performed with the input motion applied to the vertical and horizontal axis. Therefore, biaxial testing at a minimum requires twice the number of runs as triaxial testing. The preferred method for biaxial testing is independent, random tests.

For biaxial testing, when independent, random tests are not available, four tests are performed:

1. With the inputs in phase
2. With one input 180 degrees out of phase
3. With the equipment rotated 90 degrees horizontally and the inputs in phase
4. With the same orientation as in the step (3), but with one input 180 degrees out of phase

3.10.2.2.3 Selection of Test Specimen

Representative samples of equipment and supports are selected for use as test specimens. Variations in the configuration of the equipment are analyzed with supporting test data. Test specimen assemblies that represent multiple configurations are configured to represent the “worst case” configuration. For example, these variations may include mass distributions that differ from one cabinet to another. Therefore, it is analyzed and justified which mass distribution(s) results in the maximum stresses, such as response accelerations or frequency content, and this worst-case configuration(s) is used as the test specimen(s).

3.10.2.2.4 Mounting of Test Specimen

The test specimen is mounted to the test table so that the installed configuration, including interfaces, is adequately simulated and differences between the configuration are evaluated and resolved. If the test specimen is intended to be mounted to a panel or enclosure, the panel, enclosure, or a test fixture representative of the mounting conditions is included in the testing, unless justified. If the test specimen cannot be mounted directly to the table due to mounting constraints, an interposing test fixture is designed and used as the mounting interface. However, the equipment-to-fixture mounting condition is to simulate its installed configuration and cause no dynamic coupling to the equipment. If the equipment being analyzed has no required orientation, the worst possible orientation is considered. The test specimen is considered to be in its operational configuration (i.e., filled with the appropriate fluid and/or solid). The investigation ensures that the point of maximum stress is considered. The test specimen mounting, and configuration includes hardware interface requirements. For interfaces that cannot be simulated on the test table, the accelerations and any resonances at such interface locations are recorded during the equipment test and documented in the test report.

3.10.2.2.5 Aging and Vibration Conditioning

The testing simulates the effects of aging. Equipment is reviewed in terms of design, function, materials, and environment for its specified application to identify potentially significant aging mechanisms.

If equipment is subjected to vibrational loads throughout its lifetime in its inservice mounted condition, then vibration aging to its end-of-life condition is performed prior to seismic qualification when required by the applicable qualification standard(s).

3.10.2.3 Qualification by Analysis

Qualification by analysis without testing may be acceptable on equipment that is only required to maintain its structural integrity to perform its safety function as described in IEC/IEEE 60980-344.

Dynamic analysis or an equivalent static analysis is employed to qualify the equipment when analysis is chosen as the method for qualification. The decision on using dynamic versus static analysis is typically defined based on whether the equipment is rigid or flexible.

If the fundamental frequency of the equipment is above the input excitation frequency (cutoff frequency of RRS), the equipment is considered rigid. The search for the natural frequency is done analytically, if the equipment shape is defined mathematically, or by prototype testing.

If the equipment is determined to be a rigid body (i.e., shown to have no resonance frequency within the expected frequency range), the static analysis method is able to be applied in place of dynamic analysis.

If the equipment is determined to be flexible (i.e., with the fundamental frequency of the equipment within frequency range of the input spectra) and not simple enough for equivalent static analysis, a dynamic analysis method is applied, unless justified otherwise.

If it is determined either dynamic or static analysis can be used, in general, the choice of the analysis is based on the expected design margin because the static coefficient method (the easiest to perform) is far more conservative than the dynamic analysis method.

For static analysis, the dynamic forces on each component can be obtained by concentrating the mass at the center of gravity and multiplying the mass by the appropriate floor acceleration. The dynamic stresses are then added to the operating stresses and a determination is made of the adequacy of the strength of the equipment.

A static coefficient analysis may also be used for certain equipment in lieu of the dynamic analysis. No determination of natural frequencies is made in this case. The seismic loads are determined statically by multiplying the actual distributed weight of the equipment by a static coefficient equal to 1.5 times the peak value of the RRS at the equipment mounting location, at a conservative and justifiable value of damping.

Both types of analyses are to verify integrity of the equipment is maintained under low level earthquake loads, including appropriate RBV dynamic loads in combination with normal operating loads, and Safe Shutdown Earthquake (SSE) loads, including appropriate RBV dynamic loads, unless otherwise justified.

Subsection 3.9.3.1 defines acceptable load combinations and methods for combining dynamic responses for mechanical equipment. The same criteria are acceptable for electrical equipment.

3.10.2.4 Qualification by Combined Testing and Analysis

Qualification by combined testing and analysis is used as a method for qualification for complex or large equipment where it is not practical to test the entire assembly or it is too large to be tested at once, unless another method of qualification is justified.

One method of combined qualification is to use a representative prototype portion or scaled-down prototype of the assembly that is subjected to type testing. The data from the type testing is then used to develop and validate an analytical model of the prototype. The prototype analytical model is then extrapolated to represent the larger assembly and the results used to justify qualification of the equipment based on prototype testing.

A second method of combined qualification is to mount the full assembly to a rigid floor to simulate service mounting, and then a portable shaker test (or an impact or pull test if justified) is performed to excite the natural or resonance frequencies of the specimen. The amplification of resonance motion is used to determine the appropriate modal frequency and damping for a dynamic analysis of the equipment.

For equipment with multiple site configurations, the combined qualification method can be applied to reduce the number of configurations to be tested. In this case, an evaluation must be performed to determine the enveloping “worst-case” configuration(s), which is then tested. Analysis is then used to justify the various configurations based on the “worst-case” configuration(s).

The combination method is used for qualification of larger electrical equipment support assemblies containing SC1 equipment where it is not practical to test the entire assembly or it is too large to be tested at once, unless another method of qualification is justified. For this case, a test is run to determine if there are natural frequencies in the support equipment within the critical frequency range (any frequency below the cutoff frequency on the response spectrum). If the support is determined to be free of natural frequencies in the critical frequency range, then it is assumed to be rigid, and a static analysis is performed and calculations of transmissibility and responses to varying input accelerations are determined to see if SC1 equipment mounted in the assembly would operate without malfunctioning.

For digital I&C equipment qualification in a mild environment, analysis can be used in addition to testing if there is testing of an identical or similar item, or there is operating experience of equipment under identical or similar conditions with a supporting analysis to show that the equipment to be qualified is acceptable. Also, I&C equipment qualification can be performed using an analysis in combination with partial type test data that supports the analytical assumptions and conclusions.

3.10.3 Methods and Procedures of Analysis or Testing of Supports for Mechanical, Electrical Equipment and Instrumentation

Methods and procedures of analysis or testing of supports for mechanical and electrical equipment and instrumentation are in accordance with IEC/IEEE 60980-344 and ASME QME-1.

3.10.3.1 Supports for Battery Racks, Instrument Racks, Control Consoles, Cabinets, and Panels

SC1 control boards, panels, and racks should consider the qualification guidance provided in IEEE 420-2023, “IEEE Standard for Design and Qualification of Class 1E Control Boards, Panels, and Racks Used in Nuclear Power Generating Stations,” (Reference 3.10-5) for their qualification program.

3.10.3.2 Cable Trays and Conduit Supports

SC1 cables consider the qualification guidance provided in IEEE 383-2023, “IEEE Standard for Qualifying Electric Cables and Splices for Nuclear Facilities,” (Reference 3.10-6) and IEEE 384-2018, “IEEE Standard Criteria for Independence of Class 1E Equipment and Circuits,” (Reference 3.10-7), and test requirements in IEEE 1202-2006, “IEEE Standard for Flame-Propagation Testing of Wire and Cable,” (Reference 3.10-8).

Supports provided by the equipment supplier will be qualified in accordance with this section by the equipment supplier.

Seismic Category I supports (hangers) that support trays or conduit that carry SC1 circuits are designed and analyzed to demonstrate qualification in accordance with IEEE 628-2020, “IEEE Standard Criteria for the Design, Installation, and Qualification of Raceway Systems for Class 1E Circuits for Nuclear Power Generating Stations,” (Reference 3.10-9).

SC1 connection assemblies consider the qualification guidance provided in IEEE 572-2019, “IEEE Standard for Qualification of Class 1E Connection Assemblies for Nuclear Power Generating Stations and Other Nuclear Facilities,” (Reference 3.10-10) for the qualification program as endorsed by RG 1.156, “Qualification of Connection Assemblies for Production and Utilization Facilities.”

3.10.3.3 Line-Mounted Equipment

IEC/IEEE 60980-344 identifies that special consideration is required for line-mounted (piping and duct system) equipment regarding seismic qualification as the most critical seismic loading condition can occur as a result of the piping or duct system.

Guidance and further clarification for special considerations for line-mounted equipment are provided in IEC/IEEE 60980-344 as well as IEEE 382-2019, “IEEE Standard for Qualification of Safety-Related Actuators for Nuclear Power Generating Stations and Other Nuclear Facilities,” (Reference 3.10-11). Line-mounted equipment may also include active mechanical equipment subjected to ASME QME-1, including Non-mandatory Appendix QR-A.

3.11 Environmental Qualification of Mechanical and Electrical Equipment

Environmental Qualification (EQ) includes the generation and maintenance of evidence to ensure Structures, Systems, and Components (SSCs) can perform their intended design functions and remain fit for purpose in the conditions under which they are expected to perform. Section 3.10 provides the methodology and requirements used for the seismic and dynamic qualification of Seismic Category I mechanical and electrical equipment.

Mild Environment

An environment that would at no time be significantly more severe than the environment that would occur during normal plant operation, including Anticipated Operational Occurrences (AOOs), and does not give rise to significant aging mechanisms.

Harsh Environment

An environment that significantly changes from normal including design basis events and post-accident conditions as a result of a Design Basis Accident (DBA).

AOO Environment

AOO environmental conditions are the service conditions as a result of an operational deviation expected to occur during the operating plant lifetime that do not lead to accident conditions.

The methodology and requirements apply to the EQ of Safety Class 1 (SC1) mechanical and electrical equipment, including Instrumentation and Control (I&C), located in harsh and mild environments. International Electrotechnical Commission/ Institute of Electrical and Electronics Engineers (IEC/IEEE) 60780-323, “Nuclear Facilities – Electrical Equipment Important to Safety – Qualification,” (Reference 3.11-1), as endorsed by RG 1.89, “Environmental Qualification of Certain Electric Equipment Important to Safety for Nuclear Power Plants,” defines the methodology and criteria used to qualify SC1 equipment for harsh and mild environments for the BWRX-300.

The BWRX-300 design discussed in Section 3.11 complies with the following GDC, which have plant-wide applicability, as discussed in Section 3.1:

GDC 1 – Quality standards and records

GDC 2 – Design bases for protection against natural phenomena

GDC 4 – Environmental and dynamic design bases

The following GDC aspects specific to Section 3.11 and compliance is addressed as follows:

GDC 23 – Protection system failure modes. The environmental conditions in which the instrumentation and equipment of the SC1 systems operate are considered in establishing the component specifications. Instrumentation specifications are based on the worst expected

ambient environmental conditions in which the instruments operate. A list of preliminary BWRX-300 SSCs classification, their location, seismic category, and quality category is provided in Table 3A-1. Accordingly, the requirements of GDC 23 are met.

Additional Information on GDC compliance is found in Section 3.1.

Qualification of mechanical equipment that performs a safety function is in accordance with American Society of Mechanical Engineers (ASME) QME-1, “Qualification of Active Mechanical Equipment Used in Nuclear Facilities,” (Reference 3.11-2).

3.11.1 Equipment Identification and Environmental Conditions

3.11.1.1 Equipment Identification

The equipment qualification program generates and maintains a list of SC1 equipment located in harsh and mild environments. The qualification plan includes the following parameters, at minimum and as applicable: the test and/or analysis sequence, environmental and/or seismic/dynamic or Electromagnetic Compatibility (EMC) requirements, test item functions, identification of industry codes and standards applicable to equipment, identification of the test equipment including description and calibration plan, and test item part numbers, quantity, mounting, and connection details.

3.11.1.2 Environmental Conditions

3.11.1.2.1 General Requirements

Environmental Design Bases

The environmental conditions consider normal, AOO, accident, and post-accident conditions, as applicable. Equipment located below the maximum flood level considers the effects of submergence and is qualified for flooding if it is required to function in this condition. Post-accident monitoring equipment considers the criteria for accident monitoring instrumentation and EQ guidance provided in IEC 63147:2017/IEEE Std 497-2016, “Criteria for Accident Monitoring Instrumentation for Nuclear Power Generating Stations,” (Reference 3.11-3) in lieu of IEEE 497-2016 as endorsed by RG 1.97, “Criteria for Accident Monitoring Instrumentation for Nuclear Power Plants.”

The harsh environment qualification program verifies that the equipment is designed to be compatible and perform its safety functions during normal conditions, postulated environmental conditions, DBA, and post-accident conditions.

Equipment located within harsh environment conditions is exposed to environmental conditions including temperature, pressure, relative humidity, radiation, and chemical sprays.

Equipment determined to have a significant aging mechanism and located in a harsh environment account for the aging mechanism in the qualification program.

Aging mechanisms to be analyzed for equipment located in a harsh environment include time-temperature degradation (thermal), cycle aging (wear), and normal radiation exposure.

Analysis is performed to identify the environmental design bases for AOOs, normal, accident, and post-accident environments as applicable.

Equipment is qualified to the worst-case environmental conditions for the areas in which they are located for the duration that they are required to perform their Safety Category 1 function.

The Safety Category 1 functions are either functional performance requirements or fail-safe requirements. A fail-safe Safety Category 1 function consists of not failing in a manner detrimental to plant safety, accident mitigation, or prevention of a Safety Category 1 function. The basis for the Safety Category 1 function is included in the qualification documentation.

Although EQ by testing or analysis is not required for Safety Class 2 (SC2) and Safety Class 3 (SC3) components, these components are designed for their expected duty cycle and environmental conditions over the design life of the plant with due consideration for maintenance and aging management. Additionally, SC2 and SC3 components that perform a Safety Category 1 function are qualified to the specified environmental conditions by testing or analysis.

The environments are considered for electrical and mechanical equipment in the EQ program such as temperature, pressure, humidity, chemical effects, radiation, and flooding effects. The EQ program uses the recommended environmental margins per IEC/IEEE 60780-323, Table 1.

Aging requirements apply to SC1 equipment. For equipment located in harsh and mild environments, the effect of aging is be performed prior to DBA testing when a significant aging mechanism exists. Equipment is reviewed in terms of design, function, materials, and environment for its specified application to identify potentially significant aging mechanisms.

Equipment that could be exposed to radiation is environmentally qualified to a radiation dose that simulates the calculated radiation environment (normal and accident) that the equipment can withstand prior to completion of its required safety functions.

Radiation qualification considers that equipment damage is a function of total integrated dose and can be influenced by dose rate, energy spectrum, and particle type. The radiation qualification includes doses from all potential radiation sources at the equipment location. For equipment that is required to be functional post-accident, then the radiation dose is increased beyond the dose required for qualified life to envelop post-accident conditions as well, unless it is determined to cover post-accident conditions separately.

A mild radiation environment for electronic equipment is defined as a total integrated dose less than 10 gray (Gy) (1.0E03 rad), and a mild radiation environment for other equipment is less than 100 Gy (1.0E04 rad) as defined in RG 1.89.

Electronic and electrical equipment are tested with the equipment energized and performing its safety function if the required total integrated dose exceeds the mild environment level. This ensures equipment is qualified for the worst-case radiation with DBA margin per the requirements of IEC/IEEE 60780-323.

Electromagnetic Interference / Radio Frequency Interference and Voltage Surges

EMC requirements apply to all levels of safety class equipment, SC1, SC2, SC3, and Non-Safety Class (SCN) and provides qualification methods and implementation guidance. EMC qualifications for BWRX-300 design follow the requirements defined in (1) Electric Power Research Institute (EPRI) TR-102323, “Guidelines for Electromagnetic Compatibility Testing of Power Plant Equipment,” (Reference 3.11-4), or (2) Military Standards MIL-STD-461G, “Requirements for the Control of Electromagnetic Interference Characteristics of Subsystems and Equipment,” (Reference 3.11-5), or (3) IEC 62003, “Nuclear Power Plants – Instrumentation, Control, and Electrical Power Systems – Requirements for Electromagnetic Compatibility Testing,” (Reference 3.11-6). The qualification for Electromagnetic Interference/Radio Frequency Interference (EMI/RFI) and voltage surges for EQ equipment in harsh and mild environments is by test, consistent with RG 1.180, “Guidelines for Evaluating Electromagnetic and Radio-Frequency Interference in Safety-Related Instrumentation and Control Systems.” EMC Qualification and Acceptance Testing includes tests for susceptibility and emissions. Susceptibility and emissions requirements are applied to all Safety Class and SCN microprocessor-based I&C and electrical equipment.

3.11.2 Qualification Tests and Analyses

3.11.2.1 Qualification By Testing

Type testing is the preferred method for demonstrating that equipment is Environmentally Qualified. A type test subjects a representative sample of equipment, including interfaces, to a series of tests, and includes simulating the effects of significant aging mechanisms during normal operation. The sample is subsequently subjected to conditions that simulate DBA harsh conditions and thereby establishes the tested configuration for installed equipment service, including mounting, orientation, interfaces, conduit sealing, and expected environments. A type test demonstrates that the equipment performs the intended Safety Category function(s) for the required operating time before, during, and/or following the DBA, as appropriate.

Tests are performed in accordance with applicable industry standards, such as IEC/IEEE 60780-323.

3.11.2.2 Qualification by Analysis

In general, analysis is used to supplement test data and the analytical techniques and modeling assumptions are, when possible, based on a correlation of the analytical approach with testing or operating experience performed on similar equipment or structures.

Seismic and dynamic qualification by analysis is described in Subsection 3.10.2.3.

For qualification by analysis, a logical assessment, or a valid mathematical model of the equipment to be qualified is required, and the basis for the analysis includes physical laws of nature, results of test data, operating experience, and condition indicators, as applicable.

Analysis of data and tests for material properties, equipment rating, and environmental tolerance are acceptable methods to be used to demonstrate qualification.

Analysis alone is not used to demonstrate the initial qualification for electrical equipment in a harsh environment.

3.11.2.3 Qualification by Operating Experience

Qualification by use of operating experience requires documented data to be available confirming to the following conditions are met:

- The product providing the operating experience is identical or justifiably similar to the equipment to be qualified.
- The product providing the operating experience has operated under service conditions which equal or exceed, in severity the service conditions and performance requirements for which the product is to be qualified are bounded by the product providing the operating experience.
- The installed product in general, is removed from service and subjected to partial type testing to include the DBA environments for which the product is to be qualified.

3.11.2.4 Combined Qualification

Combination of test and analysis is used when it is deemed practical to use both methods to complete the qualification. The combined qualification method can be used for qualification for larger electrical equipment where it is not practical to test the entire assembly, or it is too large to be tested at once, unless another method of qualification is justified.

For digital I&C equipment qualification in a mild environment, analysis can be used in addition to testing if there is testing of an identical item of equipment under identical conditions or under similar conditions or operating experience with a supporting analysis to show that the equipment to be qualified is acceptable. Also, I&C equipment qualification can be performed using an analysis in combination with partial type test data that supports the analytical assumptions and conclusions.

3.11.2.5 Specific Equipment Requirements

3.11.2.5.1 Mechanical Equipment

SC1 mechanical equipment, which has the sole Safety Category 1 function of maintaining pressure integrity, and which is designed, fabricated, and qualified consistent with ASME Boiler and Pressure Vessel Code (BPVC), Section III, Division 1, “Rules for Construction of Nuclear Facility Components,” (Reference 3.11-7), is considered qualified.

For mechanical equipment where the loading under normal service is more severe than loading under DBA, then the loading under normal service is considered in addition to the loading under DBA by test and/or analysis.

For mechanical equipment, the loading and capability under DBA conditions is analyzed in the qualification process to establish the suitability of materials, parts, and equipment needed for safety functions, and to verify that the design of such materials, parts, and equipment is adequate.

The qualification of mechanical equipment includes, as applicable, materials that are sensitive to environmental effects (e.g., seals, gaskets, lubricants, fluids for hydraulic systems, and diaphragms), required operating time, non-metallic subcomponents of such equipment, the environmental conditions and process parameters for which this equipment is qualified, non-metallic material capabilities, and the evaluation of environmental effects.

In addition, the qualification guidance provided in ASME QME-1 is considered for qualification of SC1 valves and SC1 mechanical pipe supports. The qualification of nonmetallic parts considers the qualification guidance provided in ASME QME-1, Nonmandatory Appendix QR-B.

3.11.2.5.2 Electrical Equipment

Additional qualification guidance is considered for specific electrical equipment, if applicable, as follows:

RG 1.158, “Qualification of Safety-Related Vented Lead-Acid Storage Batteries for Nuclear Power Plants,” which endorses IEEE 535-2022, “IEEE Standard for Qualification of Class 1E Vented Lead Acid Storage Batteries for Nuclear Power Generating Stations,” (Reference 3.11-8)

RG 1.40, “Qualification of Continuous Duty Safety-Related Motors for Nuclear Power Plants,” which endorses IEEE 334-2006, “IEEE Standard for Qualifying Continuous Duty Class 1E Motors for Nuclear Power Generating Stations,” (Reference 3.11-9) if considered applicable to BWRX-300 design.

RG 1.63, “Electric Penetration Assemblies in Containment Structures for Nuclear Power Plants,” which endorses IEEE 317-2013, “IEEE Standard for Electrical Penetration Assemblies in Containment Structures for Nuclear Power Generating Stations,” (Reference 3.11-10)

RG 1.73, “Qualification Tests for Safety-Related Actuators in Nuclear Power Plants,” which endorses IEEE 382-2019, “IEEE Standard for Qualification of Safety-Related Actuators for Nuclear Power Generating Stations and Other Nuclear Facilities,” (Reference 3.11-11)

RG 1.89, “Environmental Qualification of Certain Electric Equipment Important to Safety for Nuclear Power Plants” which endorses IEC/IEEE-60780-323 that includes IEEE 638-2013 “IEEE Standard for Qualification of Class 1E Transformers for Nuclear Power Generating Stations,” (Reference 3.11-12)

RG 1.213, “Qualification of Safety-Related Motor Control Centers for Nuclear Power Plants,” considers conformance with the requirements of IEEE 649-2006, “IEEE Standard for Qualifying Class 1E Motor Control Centers for Nuclear Power Generating Stations,” (Reference 3.11-13) if considered applicable to BWRX-300 design.

RG 1.210, “Qualification of Safety-Related Battery Chargers and Inverters for Nuclear Power Plants,” which endorses IEEE 650-2006, “IEEE Standard for Qualification of Class 1E Static Battery Chargers, Inverters, and Uninterruptible Power Supply Systems for Nuclear Power Generating Stations,” (Reference 3.11-14)

3.11.2.5.3 Instrumentation & Control Equipment

Additional qualification guidance is considered for specific I&C equipment, if applicable, as follows:

- Control boards, panels, and racks classified as SC1 components – IEEE 420-2023, “IEEE Standard for Design and Qualification of Class 1E Control Boards, Panels, and Racks Used in Nuclear Power Generating Stations,” (Reference 3.11-15) for their qualification program.

Qualification of computer based I&C systems is in accordance IEEE 7-4.3.2-2016, “IEEE Standard Criteria for Programmable Digital Devices in Safety Systems of Nuclear Power Generating Stations,” (Reference 3.11-16). The EMC requirements are specified in RG 1.180.

When computer based I&C systems environmental type testing is performed:

- The system under test demonstrates that it functions and performs with safety software that has been validated and verified and is representative of the software to be installed in service.
- The testing demonstrates performance of all safety function that affected by environmental factors under the environmental service conditions specified in the design specification. Software algorithms, which are tested during Verification and Validation (V&V) testing, are not tested unless their outputs exercise different hardware components which are affected impacted by environmental conditions.
- The testing exercises all portions of the system that are necessary to accomplish the safety functions and those portions whose operation or failure could impair the safety functions.
- The testing confirms the response of digital interfaces and verifies that the design accommodates the potential effect of environmental conditions on the overall response of the system.

When computer based I&C systems environmental type testing is performed, the testing of a complete system is preferred. When testing of a complete system is not practical, confirmation of the dynamic response to the most limiting environmental and operational conditions is based on type testing of the individual modules and analysis of the cumulative effects of environmental and operational stress on the entire system to demonstrate required safety performance.

3.11.2.5.4 Cables, Raceways, Supports

For qualification of SC1 cables, the qualification guidance provided in IEEE 383-2023, “IEEE Standard for Qualifying Electric Cables and Splices for Nuclear Facilities,” (Reference 3.11-17) and IEEE 384-2018, “IEEE Standard Criteria for Independence of Class 1E Equipment and

Circuits," (Reference 3.11-18) are considered. The test requirement guidance provided in IEEE 1202-2023 "IEEE Standard for Flame-Propagation Testing of Wire and Cable," (Reference 3.11-19) is used as a qualification program.

Seismic Category I supports (hangers) that support trays or conduit that carry SC1 circuits are designed and analyzed to demonstrate qualification in accordance with IEEE 628-2020 "IEEE Standard Criteria for the Design, Installation, and Qualification of Raceway Systems for Class 1E Circuits for Nuclear Power Generating Stations," (Reference 3.11-20).

Seismic Category II supports, used for SCN raceway (conduit and cable tray) in Seismic Category I and II structures, shall be analyzed to withstand the effects of an SSE.

SC1 connection assemblies consider the qualification guidance provided in IEEE 572-2019, "IEEE Standard for Qualification of Class 1E Connection Assemblies for Nuclear Power Generating Stations and Other Nuclear Facilities," (Reference 3.11-21) as endorsed by RG 1.156, "Qualification of Connection Assemblies for Production and Utilization Facilities."

3.11.2.5.5 Line-Mounted Equipment

Guidance in IEC/IEEE 60980-344, "Nuclear Facilities Equipment Important to Safety-Seismic Qualification," (Reference 3.11-22) identifies that special consideration is required for line-mounted (pipe-supported) equipment regarding seismic qualification as the most critical seismic loading condition that occurs as a result of the piping or duct system. Guidance and further clarification for special considerations for line-mounted equipment is provided in IEEE 382-2019. Line mounted equipment also includes active mechanical equipment subjected to ASME QME-1 including Non-mandatory Appendix QR-A.

3.12 ASME Code Class 1, 2, and 3 Piping Systems, Piping Components and Their Associated Supports

Section 3.12 provides the general design aspects used for Safety Class and Non-Safety Class (SCN) piping systems, piping components and pipe supports. The design of Safety Class 1 (SC1) piping systems, piping components and pipe supports is based on the rules established under the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code (BPVC), Section III, Division 1, “Rules for Construction of Nuclear Facility Components,” for Class 1, Class 2, and Class 3 nuclear piping, components and supports. For non-SC1 components, ASME B31.1, “Power Piping” (Reference 3.12-5), ASME B31.3, “Process Piping” (Reference 3.12-6), and ASME B31.5, “Refrigeration Piping and Heat Transfer Components” (Reference 3.12-7) are used. Safety class, seismic categories, and quality groups for piping Structures, Systems, and Components (SSCs) are listed in Table 3A-1. The functional, operational, and safety requirements are unique to each system, and the required loading conditions are applied as specified in the specific ASME Code class sections.

Section 3.9 provides the general design principles, criteria, and classification used for design of mechanical systems and components.

The load combinations and acceptance criteria in Table 3.12-1 are applied to the analysis of Class 1 piping including its interfaces with components and penetrations.

The load combinations and acceptance criteria in Table 3.12-2 are applied to the analysis of Class 2 and 3 piping systems and containment penetrations.

The load combinations and acceptance criteria in Table 3.12-3 are applied to the analysis of non-nuclear (ASME B31.1) piping systems and components.

The load combinations and acceptance criteria in Table 3.12-4 are applied to the analysis of non-nuclear (ASME B31.3) piping systems and components.

The load combinations and acceptance criteria in Table 3.12-5 are applied to the analysis of ASME Class 1, 2, and 3 snubber type supports.

The load combinations and acceptance criteria in Table 3.12-6 are applied to the analysis of ASME Class 1, 2, and 3 rigid type supports.

The load combinations and acceptance criteria in Table 3.12-7 are applied to the analysis of ASME Class 1 piping connected to RPV nozzles.

The load combinations and acceptance criteria in Table 3.12-8 are applied to the analysis of ASME Class 2 piping connected to RPV nozzles.

The load combinations and acceptance criteria in Table 3.12-9 are applied to the analysis of ASME Class 1, 2, and 3 pipe-mounted valves.

The load combinations and acceptance criteria in Table 3.12-10 are applied to the analysis of ASME B31.1 and ASME B31.3 Linear Type Supports (Anchor, Guide, Struts).

The BWRX-300 design meets the relevant requirements of the following regulations:

The BWRX-300 design discussed in Section 3.12 complies with the following GDC, which have plant-wide applicability, as discussed in Section 3.1:

GDC 1 – Quality standards and records

GDC 2 – Design bases for protection against natural phenomena

GDC 4 – Environmental and dynamic design bases

The following GDC and Appendix S have aspects specific to Section 3.12 and compliance is addressed as follows:

10 CFR Part 50, Appendix S – as it relates to design transients and resulting load combinations for SC1 piping and pipe supports necessary to withstand the effects of earthquakes as discussed in Subsection 3.7.3 combined with the effects of normal or accident conditions including a LOCA and dynamic effects as defined in Table 3.12-1, Table 3.12-2, Table 3.12-3, and Table 3.12-4.

GDC 14 – Reactor coolant pressure boundary, as it relates to the Reactor Coolant Pressure Boundary (RCPB) of the piping systems being designed, fabricated, erected, and tested in accordance with the requirements in 10 CFR 50.55a, “Codes and Standards,” to have an extremely low probability of abnormal leakage, of rapidly propagating failure, and of gross rupture. The design involves meeting the acceptance criteria utilizing load combinations in Table 3.12-1 and Table 3.12-2, including transient plant duty cycles in Table 3.9-2 for the 60-year life period to assure that minimal abnormal leakage occurs.

GDC 15 – Reactor coolant system design, as it relates to the reactor coolant system and associated auxiliary, control, and protection systems being designed with sufficient margin to ensure that the design condition of the RCPB are not exceeded during any condition of normal operation, including Anticipated Operational Occurrences (AOOs). Subsections 3.9.1 through 3.9.6 provide design requirements for safety class and risk informed mechanical components and piping that meet the margin and design condition requirements, therefore complying with GDC 15.

Additional Information on GDC compliance is found in Section 3.1.

3.12.1 Piping Analysis Methods

ASME Class 1 piping design conforms to the requirements of ASME BPVC, Section III, Subsection NB (Reference 3.12-1) for both piping and piping components. The pipe supports attached to the ASME Class 1 piping meet the appropriate requirements of ASME BPVC, Section III, Subsection NF (Reference 3.12-2).

ASME Class 2 and 3 piping design conforms to the requirements of ASME BPVC, Section III, Subsection NCD (Reference 3.12-3) for both piping and piping components. The pipe supports attached to the ASME Class 2 and 3 piping meets the appropriate requirements of ASME BPVC, Section III, Subsection NF.

The containment penetration sleeve of ASME Class 2 piping is an anchor for the piping. The sleeve of the containment structure penetrations meets the requirements of ASME BPVC, Section III, Subsection NE (Reference 3.12-4). Section 3.8 and Figure 3.8-5 provide details of penetration jurisdictional boundaries.

Power piping is designed per ASME B31.1, “Power Piping,” (Reference 3.12-5) and process piping is designed per ASME B31.3, “Process Piping,” (Reference 3.12-6). Descriptions of systems that contain ASME B31.1 or ASME B31.3 piping and components including their functions are described in the system chapters.

Refrigerant piping meets the requirements of ASME B31.5, “Refrigeration Piping and Heat Transfer Components,” (Reference 3.12-7) as described in Subsection 9.2.7.

Table 3.12-1 and Table 3.12-2 provide the specific load combinations and acceptance criteria for ASME Class 1, 2, and 3 piping including its interfaces with components and penetrations. Table 3.12-3 and Table 3.12-4 provide the specific load combinations and acceptance criteria for ASME B31.1 and ASME B31.3 piping.

Supports and their attachments for ASME Class 1, 2, and 3 piping are designed in accordance with Subsection NF up to the interface of the building structure, with jurisdictional boundaries as defined by Subsection NF. The building structure component supports (connecting the Subsection NF support boundary component to the existing building structure) are designed as specified in Subsection 3.8.4.2.

3.12.1.1 Experimental Stress Analysis Methods

Standard flanges used in SC1 piping systems are in accordance with ASME B16.5, “Pipe Flanges and Flanged Fittings: Nominal Pipe Size (NPS) 1/2 Through NPS 24, Metric/Inch Standard,” (Reference 3.12-8) with high-strength bolting per NCD-3658.3.

In cases where a fitting or joint design is used that is not covered by Table NB-3681(a)-1 or NCD-3673.2(b)-1, (or if it is desired to determine less conservative values), stress intensification factors and flexibility factors are established using experimental or analytical data.

Determination of non-standard stress intensification factors and flexibility factors is in accordance with the rules of NB-3672.7.

3.12.1.2 Modal Response Spectrum Method

The seismic response of the piping system is determined by performing a modal analysis by either the Response Spectrum Method or Time History Method. The procedure for multi-support excitation is followed with both methods.

The spectral peak shifting procedures of ASME BPVC, Section III, Nonmandatory Appendix N, (Reference 3.12-9) are used for design of systems with closely spaced structural modes and artificially broadened spectra input.

Nodal points are selected to coincide with the locations of concentrated masses, locations of significant geometry changes, or locations of supports. Node points need to be sufficiently close to ensure higher modes to be captured.

The support movement of multiple-supported piping and equipment systems subject to seismic and other dynamic load excitations is considered in design verification. As a conservative approach, the maximum displacement of each support point can be computed by either time history analysis, or response spectrum analysis. The computed individual maximum support displacements are then imposed on the supported piping and equipment systems in the most limiting, or severe, directional combination for the piping and equipment design verification consideration.

Refer to Subsection 3.7.3.1.4 and Section 3.10 for discussions on modal response methods of piping.

3.12.1.3 Response Spectra Method - Independent Support Motion Method

The Independent Support Motion or Multiple Response Spectra Method is used when piping systems are supported by multiple support structures or at multiple levels within a structure. In this method of analysis, supports are divided into support groups with different seismic excitation applied to each group. A single set of response spectra is applied to all supports of each group, but different sets of response spectra are applied to different groups. Typically, a support group is made up of supports attached to the same structure, floor, or portion of a floor.

In the Independent Support Motion Method, dynamic analysis is performed by applying the appropriate response spectra at one support group at a time, with no motion applied to the other supports. The process is repeated for each support group.

The combinations of modal responses and spatial components for systems analyzed using Independent Support Motion is performed consistent with NUREG-1061, “Evaluation of Other Loads and Load Combinations.” Inertial responses from multiple groups in the same direction are combined by the Absolute Summation Method. Modal and directional responses are combined by Square-Root-of-the-Sum-of-the-Square (SRSS) method without considering closely spaced frequencies. The responses due to relative displacements at the support points are combined with the inertial responses by the SRSS method.

If the seismic inputs are known to be in-phase, the combination of responses is accomplished by the Absolute Summation Method.

See Subsection 3.7.3.1.4 for the Seismic Analysis of Piping Systems.

3.12.1.4 Time History Method

Subsection 3.7.2.6 describes the Three Components of Design Ground Motion analyses which conform to the acceptance criteria described in RG 1.92, “Combining Modal Responses and Spatial Components in Seismic Response Analysis.” The time history modal superposition, time

history direct integration, and response spectrum modal superposition methods can all be used in Multi-Support Excitation analysis. The modal and spatial combinations in the time history method are described in RG 1.92.

3.12.1.5 Inelastic Analysis Method

Piping system stresses are calculated on an elastic basis for each service level and evaluated in accordance with NB-3600 (Class 1) and NCD-3600 (Class 2 and 3) as described in Subsection 3.9.1.4.12. Inelastic analysis methods are addressed in Subsection 3.9.1.4.13. Mathematical models for piping systems reflect the static and dynamic characteristics of the system. In general, a piping system consists of pipe elements such as straight sections, fittings, bends, and valves. The piping system is supported and restrained by hangers, anchors, pipe guides, struts, box frames, snubbers, and equipment nozzles.

Large equipment, such as vessels and pumps, is typically decoupled from piping analysis at the nozzle connection.

The mass of the pipe and inline equipment is lumped at corresponding nodal locations and connected by weightless elastic beam elements to reflect the physical properties of the corresponding piping segment.

Inelastic analysis method is not used in the BWRX-300 piping design and analysis except for piping whip restraints in Subsection 3.6.2. For Class 1 piping of which shakedown is not established by meeting Equation (10) of NB-3600, the simplified elastic-plastic discontinuity analysis is performed through Equation (12) to Equation (14) of NB-3600 to limit the accumulated plastic strains. The system piping analysis model includes the valves and nozzle connections to pumps and other large equipment. Level D loads acting on the components are determined through the system piping analysis.

3.12.1.6 Non-Seismic and Seismic Category II

Subsection 3.7.3.8 describes the design of the interaction of non-Seismic Category I subsystems with SSCs that are categorized as Seismic Category I.

In certain instances, Seismic Category II piping is connected to Seismic Category I piping at locations other than a piece of equipment which, for purposes of analysis, could be represented as an anchor. The transition points typically occur at Seismic Category I valves, which may or may not be physically anchored. Because a dynamic analysis is modeled from pipe anchor point to anchor point, two options exist:

- Specify and design a structural anchor at the Seismic Category I valve and analyze the Seismic Category I subsystem
- Analyze the subsystem from the anchor point in the Seismic Category I subsystem through the valve to either the first anchor point in the Seismic Category II subsystem, or for a distance such that there are at least two seismic restraints in each of the three orthogonal directions

For either option, seismic loads are applied on all anchors and rigid supports in the model.

Where small Seismic Category II piping is directly attached to Seismic Category I piping, it may be decoupled from Seismic Category I piping following guidelines in Subsection 3.12.2.4.

3.12.1.7 Small Bore Piping Method

Small bore piping is defined as piping 50 mm and less NPS. Decoupling of small branch piping from main run piping follows decoupling criteria in Subsection 3.12.2.4. Seismic analysis of small-bore piping follows dynamic analysis methods per Subsection 3.12.1.2, or the equivalent static coefficient method if justified.

3.12.1.8 Seismic Category I Buried Piping

The BWRX-300 design does not include Seismic Category I buried piping.

3.12.2 Piping Modeling Techniques

3.12.2.1 Computer Codes

The computer programs used in the mechanical system and component analyses of the SC1 components are described in Appendix 3J and Subsection 3.9.1.2.

3.12.2.2 Dynamic Piping Model

Subsections 3.7.3.1.4 and 3.9.3 describe the analyses that are used to confirm that the Seismic Category I subsystems, including piping and supports, function during and after an earthquake.

3.12.2.3 Piping Benchmark Program

Refer to Subsection 3.12.2.1 and Appendix 3J for discussion of how the computer codes are benchmarked with the appropriate USNRC benchmarks in accordance with NEDO-11209-A, “GE Hitachi Nuclear Energy Quality Assurance Program Description,” (Reference 3.12-10).

3.12.2.4 Decoupling Criteria

Decoupling is a method of dividing or separating analysis models based on pipe size/moment of inertia. Branch lines with a run to branch moment of inertia ratio of 25 to 1 or greater are decoupled. The decoupling criteria described in Subsection 3.7.2.3.2 includes Seismic Category I subsystems which includes piping and supports. Piping design specifications use an alternative approach stated in Welding Research Council Bulletin WRC-300 Part II, “Technical Position on Damping and on Industry Practice,” (Reference 3.12-11) to decouple the subsystem.

3.12.3 Piping Stress Analysis Criteria

Piping stress criteria for ASME Class 1, 2, and 3 piping are discussed in Section 3.9, Table 3.12-1, and Table 3.12-2.

3.12.3.1 Seismic Input

Seismic Input criteria for In-Structure Response Spectra for ASME Class 1, 2, and 3 piping are discussed in Subsection 3.7.2.5.1.

3.12.3.2 Design Transients

Design transients and dynamic loading for ASME Class 1, 2, and 3 piping are covered in Subsections 3.9.1.1 and 3.9.3.1.

3.12.3.3 Loadings and Load Combinations

Table 3.12-1, Table 3.12-2, Table 3.12-3, and Table 3.12-4 provide the specific load combinations and acceptance criteria for ASME Class 1, 2, and 3 and non-nuclear class piping systems, structures, and components.

3.12.3.4 Damping Ratios

Damping values for seismically qualified ASME piping are discussed in Subsections 3.7.1.2 and 3.7.3.5.2 and provided in Table 3.7-7 for seismic damping values for piping, equipment, and equipment supports.

Floor response spectra include 15% peak broadening to account for possible variations in structural frequencies.

Floor response spectra used for the qualification of Class 1, 2, and 3 piping for dynamic loads with Level B service limits use a 3% critical damping ratio for piping greater than or equal to 300 mm NPS, and a 2% critical damping ratio for piping less than 300 mm NPS.

Floor response spectra used for the qualification of Class 1, 2, and 3 piping for dynamic loads with Level C or Level D service limits use a 4% critical damping ratio for all pipe sizes.

3.12.3.5 Combination of Modal Responses

The modal and spatial combinations in the time history method are described in RG 1.92.

3.12.3.6 High-Frequency Modes

Cutoff frequency and effect of missing mass to be considered for dynamic analysis are determined in accordance with Subsection 3.7.3.4.

The effect of the missing mass associated with the cutoff frequency is properly considered in the design of the system and the support of the structures and components.

The additional constraint forces associated with the missing mass are obtained by applying an additional force at the center of mass of the equipment. This force is conservatively calculated as the product of the total missing mass and the maximum input acceleration spectrum values beyond the cutoff frequency. A less conservative method may be used when justified.

3.12.3.7 Fatigue Evaluation for ASME Class 1 Piping

The Fatigue Evaluation for ASME Class 1 piping conforms to ASME BPVC, Section III, Subsection NB requirements as described in Subsection 3.12.3.19 and Table 3.12-1, which includes the fatigue usage and stress limits and conforms to NB-3653. The Cumulative Usage Factor (CUF) is calculated in accordance with NB-3653.5 and RG 1.207, “Guidelines for Evaluating Fatigue Analyses Incorporating the Life Reduction of Metal Components Due to the Effects of the Light-Water Reactor Environment for New Reactors.”

The number of earthquake events of SSCs for seismic fatigue effects is based on the dynamic response resulting from the occurrence of only one Safe Shutdown Earthquake (SSE) during the operating lifetime of the plant.

3.12.3.8 Fatigue Evaluation of ASME Class 2 and 3 Piping

The Fatigue Evaluation for ASME Class 2 and 3 piping conforms to ASME BPVC, Section III, Subsection NCD requirements.

In cases where a fitting or joint design is used which is not covered by Table NCD-3673.2(b)-1 (or if it is desired to determine less conservative values), stress intensification factors and flexibility factors are established using experimental or analytical data.

Determination of non-standard stress intensification factors and flexibility factors is in accordance with the rules of NCD-3673.2.

Expansion and flexible hoses are designed in accordance with the requirements of NCD-3649. Expansion joints and flexible hoses are subject to limitations in displacement during operation. The component manufacturer provides these displacement limits. The displacement values obtained from the stress analysis are reviewed to ensure that the specified displacement limits have not been exceeded.

3.12.3.9 Thermal Oscillations in Piping Connected to the Reactor Coolant System

As described in USNRC Bulletin 88-08, thermal fatigue of unisolable piping connected to the Reactor Coolant System (RCS) can occur when the connected piping is isolated by a leaking block valve, the pressure upstream from the block valve is higher than RCS pressure, and the temperature upstream is significantly cooler than RCS temperature. An unrecognized phenomenon and possibly unanalyzed condition may exist for those reactors that are subjected to these conditions. Under these conditions, thermal fatigue of the unisolable piping can result in crack initiation. If these conditions are identified, a program meeting the criteria in Bulletin 88-08, which provides continued assurance that piping will not be subjected to unacceptable thermal stresses, will be developed.

3.12.3.10 Thermal Stratification

Transient loading due to hot and cold fluid not mixing at low flow conditions is considered in the design of the piping. Stresses due to the effects of thermal stratification are evaluated using ASME BPVC, Section III, Nonmandatory Appendix JJ. On run/branch connections where there is a closed valve and the resulting “dead leg” temperature tends toward ambient, the temperature distribution in the run/branch line is considered and properly included in the thermal expansion analysis.

The stresses and fatigue associated with thermal stratification and thermal striping are considered in the piping analyses that demonstrate compliance within ASME Class 2 and 3 code limits. The global effect of thermal stratification causes the bending of the piping system due to the temperature distribution in the element cross section. Consequently, this generates extra thermal stress in the load combination as defined in Table 3.12-2.

3.12.3.11 Safety Relief Valve Design, Installation, and Testing

No ASME Class 1, 2, or 3 safety relief valves are in the BWRX-300 design. Subsection 3.9.3.2 describes the installation of BWRX-300 overpressure protection pressure relief devices.

If ASME Class 1, 2, and 3 safety relief valves are required, design follows the criteria for pressure relief installations specified in ASME BPVC, Section III, Nonmandatory Appendix O. In addition, the following criteria are evaluated:

- Where more than one valve is installed on the same pipe run, the sequence of valve openings to be assumed in analyzing for the stress at any piping location is that sequence which is estimated to induce the maximum instantaneous value of stress at that location.
- Stresses are evaluated, and applicable stress limits are satisfied for all components of the pipe run and connecting systems and the pressure relief valve station, including supports and all connecting welds between these components.
- In meeting the stress limit requirements, the contribution from the reaction force and the moments resulting from that force include the effects of a Dynamic Load Factor (DLF) or use the maximum instantaneous values of forces and moments for that location as determined by the dynamic hydraulic/structural system analysis. This requirement is satisfied in demonstrating satisfaction of design limits at all locations of the pipe run and the pressure relief valve for Class 1, 2, and 3 piping. A DLF of 2.0 may be used in lieu of a dynamic analysis to determine the DLF.

In the case that a Class 1 piping system is designed without a safety relief valve, the overpressure protection design follows NB-7120(c).

In the case that a Class 2 or 3 piping system is designed without a safety relief valve, the overpressure protection design follows NCD-7120(c).

3.12.3.12 Functional Capability

Functional capability for ASME Service Level D load conditions is discussed in Subsection 3.9.1.4 and is applicable to SC1 SSCs.

If the requirements of NUREG-1367, “Functional Capability of Piping Systems,” are applicable, functional capability of ASME Class 1, 2, and 3 piping systems essential for the safe shutdown under postulated events is ensured provided the following requirements are met:

- The conditions of the equation in NB-3652, Equation (9) are met for Service Level C and D loads, (Class 1)
- The conditions of the equation in NCD-3653.1(a)(9a) are met for Service Level C and D loads, (Class 2 and 3)
- Dynamic moments are calculated using an elastic response spectrum analysis with +/- 15% peak broadening and with no more than 5% damping
- Steady state (weight) stress is less than or equal to 25% of yield stress
- The ratio of pipe diameter to wall thickness is less than or equal to 50
- External pressure is less than or equal to internal pressure

3.12.3.13 Combination of Inertial and Seismic Anchor Motion Effects

Combination of inertial and seismic anchor motion effects is discussed in Subsections 3.7.3.9 and 3.7.3.1.4.

3.12.3.14 Operating Basis Earthquake as a Design Load

The BWRX-300 design considers Operating Basis Earthquake (OBE) and site operating earthquake loads as 1/3 of the site SSE. In accordance with Appendix S to 10 CFR 50, design load combinations that consider OBE and site operating earthquake loads are not required, except for the design of metal containment components where the OBE loads are considered for post-flooding condition and cyclic loading considerations, as noted in Subsection 3.7.1.1.

3.12.3.15 Welded Attachments

The piping system and pipe supports are designed and located to minimize the necessity for welded attachments to the pipe. Where welded attachments exist, local stress evaluations are performed.

The code requirements are met with the local stress added to the regular piping stress.

The local stresses are evaluated per ASME BPVC, Section III, Nonmandatory Appendix Y (Reference 3.12-9).

Use of stiff pipe clamps may result in local pipe stresses. Stiff pipe clamps described in Issue 89 of NUREG-0933, “Resolution of Generic Safety Issues,” are not used.

3.12.3.16 Modal Damping for Composite Structures

Modal Damping for Composite Structures is defined in Subsection 3.7.1.2.

Modal damping is addressed in Tables 3.7-5 and 3.7-6.

3.12.3.17 Temperature for Thermal Analyses

The analysis of thermal expansion includes all thermal operating modes, environmental conditions, cold water modes, and thermal attenuation.

Sufficient thermal expansion cases are established to account for various operating conditions to determine the maximum range of thermal expansion stresses.

The thermal stress-free state for the piping systems is defined as a temperature of 21°C (70°F) unless a basis is provided to use a higher temperature in accordance with ASME BPVC, Section III.

Applicable equipment nozzle movements are considered for their effect with respect to each operating mode. Radial and vertical movements of the RPV nozzles are considered in the thermal analysis.

For Class 1 piping systems, the moduli of elasticity are listed in ASME BPVC, Section II, “Materials,” Part D, Subpart 2, Table TM (Reference 3.12-12).

Flexibility calculations of the forces and moments in a piping system due to thermal expansion and end motions are based on the hot modulus of elasticity E_h. However, the expansion stresses computed from the forces and moments are multiplied by the ratio of the cold modulus of elasticity E_c and the hot modulus, E_c/E_h in accordance with NB-3672.5.

For Class 2 and 3 piping systems, the moduli of elasticity are listed in the applicable tables of ASME BPVC, Section II.

For non-nuclear (ASME B31.1) piping systems, the moduli of elasticity are listed in ASME B31.1, Appendix C.

For non-nuclear (ASME B31.3) piping systems, the moduli of elasticity are listed in ASME B31.3, Appendix C.

Calculation of expansion stress is based on the modulus of elasticity at room temperature.

3.12.3.18 Intersystem Loss-of-Coolant Accident

The design includes consideration of high energy and moderate energy fluid system piping located inside and outside of containment. Design bases and measures used to protect these SSCs, referred to in the following subsections as essential SSCs, are discussed in Subsections 3.6.1 and 3.6.2.

To the extent practical, low-pressure systems (e.g., systems and subsystems connected to the RCS which extend outside the primary containment boundary and including valve stem seals, pump seals, HX tubes) are designed to withstand full RCS pressure. For those interfacing systems or subsystems which do not meet the full RCS Ultimate Rupture Strength requirement, the degree and quality of isolation or reduced severity of the potential pressure challenges are low enough to preclude an intersystem LOCA.

3.12.3.19 Effects of Environment on Fatigue Design

Refer to Subsection 3.9.3.1 which describes the design bases which includes the fatigue analysis.

Class 1 piping is evaluated for the effects of fatigue as a result of pressure and thermal transients and other cyclic events including earthquakes.

Without considering exemption for the seismic fatigue analysis, the seismic fatigue usage factor is determined from Equations 11 and 14 in NB-3653.2 and NB-3653.6, respectively. This fatigue factor is added to the fatigue usage factor associated with Levels A and B load ranges to obtain the CUF factor with the minimum number of cycles for the maximum peak response levels taken as 25 Cycles for floor-supported piping and 20 Cycles for ground-supported systems.

The CUF is calculated in accordance with NB-3653.5 combined with the environmental effects per RG 1.207.

3.12.4 Piping Support Design

Pipe support types include anchor, spring hanger, snubber, strut, and supporting steel frame.

Anchor type supports provide six-way restraints to a pipe. Spring hanger type supports are used to carry the dead weight of a pipe. Snubber type supports restrain a pipe in a seismic event but allow thermal displacement during normal operation. Strut type supports restrain pipe movements for all conditions. Supporting frames are usually used to support a standard support item and/or to restrain a pipe in a single or in multiple directions.

Pipe Whip Restraints are not in the jurisdictional boundary of ASME BPVC, Section III, Subsection NF, ASME B31.1, or ASME B31.3 and thus are not considered as pipe supports and are not within the scope of this section.

Pipe supports are designed and qualified to satisfy stiffness values used in the piping analysis. For struts and snubbers, the stiffness to consider is the combined stiffness of strut, snubber, pipe clamp, and piping support steel.

Steamline supports are designed for water-filled line loads under static loading conditions that may be encountered in plant operations. In addition, provisions are made for conveniently supporting the deadweight loads imposed during hydrostatic test of the Main Steam piping.

The stiffness of the building steel/structure (i.e., beyond the Subsection NF jurisdictional boundary) is not considered in pipe support overall stiffness. Response spectra input to the piping system include flexibility of the building structure. When attachment to a building structure is not possible, any intermediate structures are included in the analysis of the pipe support.

For multi-supported systems subjected to Independent Support Motion, the Independent Support Motion method of analysis can also be performed using the time history method.

3.12.4.1 Pipe Support Applicable Codes

The pipe supports attached to the ASME Class 1 piping meet the appropriate requirements of ASME BPVC, Section III, Subsection NF.

The pipe supports attached to the ASME Class 2 and 3 piping meet the appropriate requirements of ASME BPVC, Section III, Subsection NF.

The pipe supports attached to the non-nuclear (ASME B31.1) piping meet the requirements of Sections 120 and 121 of ASME B31.1.

The pipe supports attached to the non-nuclear (ASME B31.3) piping meet the requirements of Section 321 of ASME B31.3.

3.12.4.2 Pipe Support Jurisdictional Boundaries

Support design jurisdictional boundaries at interfaces with piping, structure, or intervening elements are defined in NF-1130. If piping supports transmit loads to surface-mounted baseplates as discussed in NF-1132(d), the baseplates are within the building structure jurisdiction. Refer to Subsection 3.9.3.15.

3.12.4.3 Pipe Support Loads and Load Combinations

The design loading is established considering plant and system operating conditions anticipated or postulated to occur during the intended service life of the component, system, or structure. The criteria are described in Subsection 3.9.3.

Component and system piping loads and load combinations are provided in Table 3.12-1, Table 3.12-2, Table 3.12-3, Table 3.12-4, Table 3.12-5, and Table 3.12-6.

3.12.4.4 Pipe Support Baseplate and Anchor Bolt Design

Aspects of the anchor bolt design, including baseplate flexibility and factors of safety are used in the development of anchor bolt loads, as addressed in USNRC Bulletin 79-02, Rev.2, “Pipe Support Base Plate Design Using Concrete Expansion Anchor Bolts,” and per NF-1132(d).

3.12.4.5 Use of Energy Absorbers and Limit Stops

ASME BPVC, Section III component supports are designed, manufactured, installed, and tested in accordance with applicable codes and standards. Supports include hangers, snubbers, struts, spring hangers, frames, energy absorbers and limit stops. Pipe whip restraints are not considered as pipe supports. If energy absorbers and limit stops are required for use in the piping system, the design methodology and acceptance criteria are defined and approved. The evaluation consists of iterative response spectra analyses of the piping and support system.

3.12.4.6 Use of Snubbers

Snubber type supports are used when restraint is needed for dynamic type loading such as seismic or relief valve discharge at a location in the pipe that has large thermal movement. Snubbers are only active during dynamic events. Snubbers allow free thermal movement during normal operation and therefore are not loaded during normal operation. Due to maintenance concerns, the use of snubbers is minimized or avoided.

Snubbers are modeled with an equivalent stiffness based on dynamic tests or on data provided from the vendor. The permissible loads that the piping system can place on snubbers is defined in ASME BPVC, Section III, Subsection NF.

The load combinations and acceptance criteria applied to the analysis of snubber type supports.

3.12.4.7 Pipe Support Stiffness

Rigid supports are sized and qualified for a specified deflection limit for all conditions in the restraint directions. Where the support deflection cannot meet the minimum criteria, the actual support stiffness is developed and either justified as sufficiently rigid or included in the piping analysis. In the event the actual stiffness is included, all supports within the stress case boundary are evaluated with actual stiffness values.

3.12.4.8 Seismic Self-Weight Excitation

For the component type supports (e.g., snubbers, struts, spring hangers), support component weights may be neglected if it is demonstrated that the support is dynamically rigid or that one half of the support mass is less than 10% of the mass of the straight pipe segment of the span at the support location, to preclude amplification. Otherwise, piping supports are evaluated to include the effect of self-weight excitation on the support structure and anchorage, in detail, along with piping analyzed loads where this effect is significant.

Subsection 3.7.3.1 discusses the seismic analysis methodology used to analyze Seismic Category I components, piping, and their supports to function as needed during and after an earthquake.

3.12.4.9 Design of Supplementary Steel

The design of structural steel for use as frame type pipe supports are linear supports as defined in ASME Code, Section III, Subsection NF.

3.12.4.10 Consideration of Friction Forces

The friction force on the pipe during axial movement is considered in the design of the support.

3.12.4.11 Pipe Support Gaps and Clearances

Small gaps are provided for frame type supports allowing for radial thermal expansion of the pipe without imposing any thermal binding and to restrain the pipe.

3.12.4.12 Instrumentation Line Support Criteria

The instrumentation line supports attached to the ASME Class 1 piping meet the appropriate requirements of ASME BPVC, Section III, Subsection NF.

Subsection 3.9.1.4.5 discusses the instrumentation line support criteria for faulted conditions. Design loads and load combinations for fixed mechanical equipment are provided in Table 3.9-3 which also applies to Seismic Category I instrumentation and electrical equipment.

3.12.4.13 Pipe Deflection Limits

Rigid supports are sized and qualified for a specified deflection limit for all conditions in the restraint directions. Where the support deflection cannot meet the minimum criteria, the actual support stiffness is developed and either justified as sufficiently rigid or included in the piping analysis. In the event the actual stiffness is included, all supports within the stress case boundary are evaluated with actual stiffness values.

3.12.4.14 Clamp-Induced Local Pipe Stress Evaluation

The piping system and pipe supports are designed and located to minimize the necessity for welded attachments to the pipe. Where welded attachments exist, local stress evaluations are performed. The code requirements are met with the local stress added to the regular piping stress.

The local stresses are evaluated per ASME BPVC, Section III, Nonmandatory Appendix Y.

The use of stiff pipe clamps may result in local pipe stresses. Stiff pipe clamps described in Issue 89 of NUREG-0933 are not used.

Table 3.12-1 Load Combinations and Acceptance Criteria for ASME Class 1 Piping

Condition	Load Combination for all Terms	Acceptance Criteria	ASME Code Reference
Design	Design Pressure + Weight + Sustained Mechanical Load (Note 1)	Eq 9 ≤ 1.5 S_m	NB-3652
Service Levels A and B (Note 2)	Peak Pressure + Weight + Sustained Mechanical Load + Thermal Expansion + AOO (Note 3) + SSE (Note 4)	Eq 10 ≤ 3.0 S_m or Eq 12 & 13 ≤ 3.0 S_m and Fatigue CUF < 1.0 and Range ΔT_1 = Allowable (Note 5)	NB-3653.1 NB-3653.6 NB-3653.1 to NB-3653.6 NB-3653.7
Service Level B	Peak Pressure + Weight + AOO	Eq 9 ≤ 1.8 S_m, not greater than 1.5 S_y (Note 6) and Peak Pressure ≤ 1.1P_a	NB-3654.2(a) NB-3654.1
Service Level C	Peak Pressure + Weight + Design Basis Accident (DBA) Where DBA can be one of items as listed below: 1. Emergency Level Transient 2. Anticipated Transient Without Scram (ATWS) 3. Small Break Loss-of-Coolant Accident (SBLOCA)	Eq 9 ≤ 2.25 S_m, not greater than 1.8 S_y (Note 7)(Note 8) and Peak Pressure ≤ 1.5 P_a	NB-3655.2(a) NB-3655.1
Service Level D	Peak Pressure + Weight + DBA Where DBA can be one of items as listed below: 1. SBLOCA + SSE 2. Large Break LOCA + SSE 3. Faulted Level Transient	Eq 9 ≤ 3.0 S_m, not greater than 2.0 S_y (Note 9) (Note 10) and Peak Pressure ≤ 2.0 P_a (Note 10) and Stress caused by Seismic Anchor Movement due to SSE satisfies NB-3656(b)(4)	NB-3656(a)(2) NB-3656(a)(1) NB-3656(b)(4)

Notes:

(1) Effect of sustained mechanical load is considered together with pressure and weight. In normal operation load, fluid flow (including Flow-Induced Vibration when applicable), thermal and fluid reaction forces, and the like, are considered together with pressure and weight.

(2) Load combination is required to set up individual load set. Acceptance criteria for stress range including Equations 10, 12, and 13 are checked for each pair of load sets. One of the load sets included is that corresponding to zero pressure, zero moment, and room temperature.

(3) An event category assigned to a Postulated Initiating Event (PIE) or event sequence with an expected frequency of 1/yr to 1.0 E-02/yr that represents a deviation from normal operation but does not evolve into a postulated accident.

(4) SSE is only used for piping fatigue analysis. For piping fatigue analysis, the full range of SSE maximum stress cycles are considered. Use 25 Cycles for floor-supported piping and 20 Cycles for ground-supported systems. SSE includes both Inertia Effect and Anchor Displacement Loads, which are combined using SRSS method.

(5) NB-3653.7 provides a variable limit of the linear thru-wall gradient, based on material properties, to prevent progressive deformation due to thermal stress ratcheting.

(6) This criterion is for Service Level B loadings that do not include reversing dynamic loads (NB-3622.2) or have reversing dynamic loads combined with non-reversing dynamic loads (NB-3622.4). For Level B loadings that include reversing dynamic loads that are not required to be combined with non-reversing dynamic loads, the above criterion for Levels A and B loadings applies.

(7) If the anchor motion due to reversing dynamic loads is excluded from NB-3654, it is assessed through the requirements of NB-3656(b)(4) using 70% of the allowable.

(8) As an alternative requirement for Level C loadings that include reversing dynamic loads that are not required to be combined with non-reversing dynamic loads, the requirements of NB-3656(b) are satisfied using the allowable stress in NB-3656(b)(2), 70% of the allowable stress in NB-3656(b)(3), and 70% of the allowable loads in NB-3656(b)(4). If the anchor motion due to reversing dynamic loads is excluded from Equation (9), it is assessed through the requirements of NB-3656(b)(4) using 70% of the allowable.

(9) If the anchor motion due to reversing dynamic loads is excluded from NB-3654, it is assessed through the requirements of NB-3656(b)(4).

(10) See alternative requirements in NB-3656(b).

(11) Nomenclature:

- AOO Anticipated Operational Occurrences
- DBA Design Basis Accident
- P_a Calculated maximum allowable internal pressure for a straight pipe that is at least equal the Design Pressure
- S_A Allowable stress range for expansion stresses = f (1.25 S_c+ 0.25 S_h), where f = stress range reduction factor for cyclic conditions
- S_c Basis material allowable stress at minimum (cold) metal temperature
- S_h Basis material allowable stress at maximum (hot) metal temperature
- S_m For Eq 9, allowable design stress intensity value at a temperature consistent with the loading under consideration; for Eq 10, 12 and 13, average of the allowable stress intensity value for the highest and the lowest temperature of the metal during the transient.
- S_y Yield Strength
- SRSS Square-root-of-the-sum-of-the-squares
- TE Thermal Expansion Range in Normal and Upset Conditions

- $\Delta T1$ Value of the range of the temperature difference between the temperature of the outside surface To and the temperature of the inside surface Ti of the piping product assuming moment generating equivalent linear temperature distribution.

Table 3.12-2 Load Combinations and Acceptance Criteria for ASME Class 2 and 3 Piping

Condition	Load Combination for all Terms	Acceptance Criteria	ASME Code Reference
Design	Design Pressure + Weight + Sustained Mechanical Load (Note 1)	Equation 8 ≤ 1.5 S_h	NCD-3652
Service Levels A and B	Thermal Expansion	Equation 10a ≤ S_A (Note 2)	NCD-3653.2
Service Levels A and B	Single Non-repeated Anchor Movement	Equation 10b ≤ 3.0 S_C	NCD-3653.2
Service Levels A and B	Design Pressure + Weight + Sustained Mechanical Load + Thermal Expansion (Note 1)	Equation 11 ≤ (S_h + S_A) (Note 2)	NCD-3653.2
Service Level B	Peak Pressure + Weight + AOO (Note 3) Where AOO can be the item as listed below: 1. AOO Plant/System Upset	Equation 9 ≤ 1.8 S_h, but not greater than 1.5 S_y (Note 4)	NCD-3653.1
Service Level C	Peak Pressure + Weight + DBA Where DBA can be one of items as listed below: 1. Emergency Level Transient 2. ATWS 3. SBLOCA	Equation 9 ≤ 2.25 S_h, but not greater than 1.8 S_y (Note 5) (Note 6)	NCD-3654.2
Service Level C	Peak Pressure	Peak Pressure ≤ 1.5 P_a	NCD-3654.1
Service Level D	Peak Pressure + Weight + DBA Where DBA can be one of items as listed below: 1. SBLOCA + SSE 2. Large Break LOCA + SSE 3. Faulted Level Transient	Equation 9 ≤ 3.0 S_h, but not greater than 2.0 S_y (Note 7) (Note 8)	NCD-3655
Service Level D	Seismic Anchor Movement due to SSE	Equation in NCD-3655(b)(4)	NCD-3655
Service Level D	Peak Pressure	Peak Pressure ≤ 2.0 P_a	NCD-3655

Notes:

(1) Effect of sustained mechanical load is considered together with pressure and weight. In normal operation load, fluid flow (including Flow-Induced Vibration when applicable), thermal and fluid reaction forces are considered together with pressure and weight.

(2) Meet either Equation 10a or 11.

(3) An event category assigned to a PIE or event sequence with an expected frequency of 1/year to 1.0 E-02/year that represents a deviation from normal operation but does not evolve into a postulated accident.

(4) If the anchor displacement due to dynamic loads is excluded from Equation 9, it is included in Equation 10a or 11.

(5) Service Loadings, which Level C Service Limits are designated for, includes reversing dynamic loads that are not required to be combined with non-reversing dynamic loads.

(6) If the anchor motion due to reversing dynamic loads is excluded from Equation 9, it is assessed through the requirements of NCD-3655(b)(4) using 70% of the allowable.

(7) Service Loadings, which Level D Service Limits are designated for, includes reversing dynamic loads that are not required to be combined with non-reversing dynamic loads.

(8) If the anchor motion due to reversing dynamic loads is excluded from Equation 9, it is assessed through the requirement of NCD-3655(b)(4).

(9) Nomenclature:

- AOO Anticipated Operational Occurrences
- DBA Design Basis Accident
- P_a Calculated maximum allowable internal pressure for a straight pipe that is at least equal the Design pressure
- PD Design Pressure
- PP Peak Pressure Operating Pressure associated with Transient
- TE Thermal Expansion Range in Normal and Upset Conditions
- SBLOCA Small Break LOCA
- SSE Safe Shutdown Earthquake. Includes both inertial and displacement components which are combined using SRSS method.
- S_A Allowable stress range for expansion stresses = f (1.25 S_c+0.25 S_h), where f = stress range reduction factor for cyclic conditions.
- S_c Basic material allowable stress at minimum (cold) metal temperature
- S_h Basic material allowable stress at maximum (hot) metal temperature
- S_y Yield Strength

Table 3.12-3 Load Combinations and Acceptance Criteria for ASME B31.1 Piping and Components (Sheet 1 of 2)

Description	Load Combination	Acceptance Criteria	ASME Code Reference
Sustained	Design Pressure + Weight + Other Mechanical Loads	Eq 15 ≤ 1.0 S_h	ASME B31.1, Paragraph 104.8.1
Occasional	Design Pressure + Weight + Other Mechanical Loads + Seismic Seismic event includes but is not limited to: • SSE	Eq 16 ≤ k S_h (Note 1)	ASME B31.1, Paragraph 104.8.2 (Reference 3.12-5)
Occasional	Design Pressure + Weight + Other Mechanical Loads + Occasional event other than Seismic Occasional event includes but is not limited to: • AOO Plant/System Upset (Note 2) • Emergency Level Transient • ATWS • SBLOCA • Large Break LOCA • Faulted Level Transient • Wind • Snow Load	Eq 16 ≤ k S_h (Note 1)	ASME B31.1, Paragraph 104.8.2
Thermal Expansion and other Cyclic Load	Displacement Stress Range	Eq 17 ≤ f (0.25 S_h + 1.25 S_C (Note 3) (Note 4)	ASME B31.1, Paragraphs 104.8.3 and 102.3.2(b)(1)
Noncyclic Displacement	Noncyclic Displacement Stress Range	Eq 17 ≤ 3.0 S_C (Note 5)	ASME B31.1, Paragraph 102.3.2(b)(2)
Test	Test Pressure	Circumferential (hoop) stress ≤ 0.9 * Yield Stress	ASME B31.1, Paragraph 102.3.3 (B)

Table 3.12-3 Load Combinations and Acceptance Criteria for ASME B31.1 Piping and Components (Sheet 2 of 2)

Description	Load Combination	Acceptance Criteria	ASME Code Reference
Test	Test Pressure + Weight	Longitudinal stress ≤ 0.9 * Yield Stress	ASME B31.1, Paragraph 102.3.3 (B)

Notes:

(1) For conventional piping in accordance with ASME B31.1 rules, the k factor in the equation for stresses due to occasional loads including seismic loading is increased to 1.8. Alternatively, a conservative approach can be adopted in which the seismic stresses in the stress combination for occasional loads can be multiplied by factor 2/3 with the k factor equal to 1.2.

(2) An event category assigned to a PIE or event sequence with an expected frequency of 1/year to 1.0 E-02/year that represents a deviation from normal operation but does not evolve into a postulated accident.

(3) Stated Equation 17 of ASME B31.1 allowable stress is assuming a cycle stress range factor of 1 if total number of cycles is below 7,776. If total number cycles for displacement range exceeds 7,776 (ASME B31.1, Paragraph 102.3.2 (b)(1c)) then a factor less than 1.0 is calculated per Equation 1C in Section 102.3.2 and applied to the allowable stress.

(4) When S_h is greater than S_L, the difference between them may be added to the term 0.25 S_h, and the allowable stress range is calculated by $S_A = f (1.25 S_C + 1.25 S_h - S_L)$.

(5) Replace M_C with the moment range due to the noncyclic movement in Equation 17 to calculate the displacement stress range, S_E.

(6) Nomenclature:

- Sh Basis material allowable stress at maximum (hot) metal temperature
- Sc Basic material allowable stress at minimum (cold) metal temperature
- Sy Yield Strength

Table 3.12-4 Load Combinations and Acceptance Criteria for ASME B31.3 Piping and Components (Sheet 1 of 2)

Description	Load Combination	Acceptance Criteria	ASME Code Reference
Sustained	Design Pressure + Weight + Other Mechanical Loads	Eq 23a ≤ 1.0 S_h (Note 1)	ASME B31.3, Paragraph 320.2
